When **coughing** causes **insomnia**

IN TRACHEITIS and bronchitis the sleeplessness caused by a persistent, unproductive cough can be very exhausting. Tusana Cocillana Cough Linctus is very valuable in such cases. It provides a blend of expectorants to loosen the tenacious mucus in the upper air passages and the central sedative, codeine, to depress the cough reflex.

By breaking the vicious circle of coughing and irritation, Tusana allows the patient to sleep and gather strength for recovery. The tendency of codeine to cause constipation is offset by the inclusion of a little extract of senna in the formula.

Supplied in bottles of 4 fl. oz.

The
First
Test

of an analgesic is the rapidity with which it relieves pain.

HYPON Tablets — by virtue of their rapid disintegrating properties — merit a high score.

THE SECOND TEST of an analgesic is the absence of the unpleasant side effects of depression and constipation. These reactions do not occur with HYPON Tablets due to the presence in the formula of caffeine and phenolphthalein.

HYPON Tablets stand firm in the field of those analgesics prescribed for the relief of pain associated with rheumatic conditions, spastic dysmenorrhœa and neuralgia.

The Treatment of Asthenia

Bulk manufacturing process

Full and rapid recovery from illness or following surgical operations may be the more readily achieved if liver extract, iron and vitamins are supplied to the patient to facilitate blood regeneration. Even a relatively small fall in the hæmoglobin level in patients otherwise reasonably healthy may manifest itself in the form of general asthenia and proneness to fatigue. HEPRONA, a preparation containing Hepatex liver extract, iron, members of the Vitamin B

complex and glycerophosphates, is an excellent tonic in such cases and is suitable both for adults and children.

Manufactured under strict technical control. Each batch is pharmaceutically assayed. Tablets shown here full size.

HEXOPHENE Surgical Soap is supplied only against medical prescription. It is not sold direct to the lay public.

A Notable Advance in Aseptic Technique

For the surgical scrub; pre-operative and post-operative preparation of patients' skin; general hospital use; and for routine prophylaxis in the reduction of pyogenic skin infections.

Extensive clinical research has clearly established that regular use of soaps containing 2% hexachlorophene, a new chlorinated bisphenol, reduces the resident bacterial flora of the skin to about 5% of its ordinary level. And, further, that this low total flora is maintained during, and for a period after, regular daily use.

This bactericidal effect derives from the adsorption of hexachlorophene by the skin during the wash. HEXOPHENE Surgical Soap incorporates 2% hexachlorophene, combined with an anionic wetting agent, in a bland,

emollient soap-base especially prepared for surgical use. It quickly lathers in any water.

By the regular use of HEXOPHENE Surgical Soap the routine 10-minute pre-operative scrub can safely be reduced to 3 minutes and the scrub-brush and alcohol rinse eliminated. Brief use between operations main-

tains the low bacterial count.

HEXOPHENE Surgical Soap may also be used advantageously for the preparation of patients' skin in elective surgery; as an effective prophylactic in decreasing the incidence of pyogenic skin infections; in obstetrics (particularly domiciliary); for minor surgery (casualty and accident rooms); for general ward use and in general practice as a safeguard against contact infection; and in the field of industrial health. HEXOPHENE Surgical Soap is economical in use and shows substantial saving both in time and material costs.

A potent alkaloidal fraction of Veratrum viride — biologically standardised for hypotensive activity in mammals — a new active principle not heretofore available, for the treatment of hypertension.

An entirely new drug, Veriloid presents only the hypotensive ester alkaloids of Veratrum viride freed from the irritant and inert dross of the crude root. This active principle, because it is biologically standardised, is absolutely uniform in its pharmacological action.

Individualisation of dosage is essential for maximum therapeutic benefit. In the majority of patients the average daily requirement of 9 to 15 mg. given in divided dosage three times daily leads to a clinically significant drop in arterial tension brought about by relaxation of the smaller arterioles. This effect is readily maintained for as long as the drug is given, for tolerance to Veriloid usually does not develop. Concomitantly, gratifying subjective improvement is discernible by the patient.

Veriloid has been found effective in malignant hypertension, severe essential hypertension and in moderate elevation of the blood pressure. It is available on prescription through all pharmacies in slow dissolving tablets containing 1.0 mg., in bottles of 100. Veriloid may be prescribed on Form E.C.10 without restriction.

TISSUE REACTIONS TO PROTEIN SENSITIZATION*

BY

J. R. SQUIRE, M.D., F.R.C.P.

Leith Professor of Experimental Pathology, University of Birmingham

As this account is in no way intended to be exhaustive, but rather to illustrate the scientific basis of medicine in one field, it will not be out of place briefly to consider the nature of the processes by which science is built. They may be represented diagrammatically:

The starting-point has always been an observation, usually made in the midst of some practical performance—in medicine, when caring for a patient or examining his body after death. This clinical observation (often associated with others made previously) leads to the formulation of a hypothesis on how the events happened or what was the relation between one observation and another. In scientific medicine such hypotheses are tested by experiment, an attempt being made to reproduce the events observed at will or to replace them by some other event. The success or failure of these efforts leads on to fresh modified hypotheses—sometimes also modified by further observations—and so the cycle goes on. Increasingly, knowledge based on facts replaces speculation.

Much has been written about the nature both of observations and of experiments, good and bad, and there is still much to be learned about these aspects of scientific method. Rather less attention has been paid to the scientific hypothesis. Here only two points can be stressed. In the first place, every effort should be made to keep separate in one's mind the facts of observation and experiment from the theory or hypothesis. This is more easily said than done, for even the description of a fact may lead to hypothetical ideas slipped in with the very words used. Secondly, the distinguishing feature of a good hypothesis is its usefulness, perhaps even more than its ultimate truth. Useful hypotheses are precise and point to crucial experiments which can be performed with the resources available. The remark-

able success of most outstanding men of science—and clinical science is no exception—has been due in no small part to their flair for formulating the relevant and right hypothesis at the right time.

To illustrate this scientific basis of medicine in the field of protein sensitization we should try to proceed always from observations on man rather than on animals, and from the "known" (or relatively well understood) phenomena to the "unknown" (or more obscure). With this in mind, I propose to discuss two groups of reactions only, those of the *asthma-hay-fever-urticaria* type, and those showing reactions of the *tuberculin-trichophyton* type. Together they include a wide range of diseases and disease processes. They omit types of reaction of great interest, such as serum sickness or homograft reactions—although a good scientific basis has now been established for discussing the nature of these processes. It is also necessary to omit many disordered functions classified to-day as rheumatic fever, polyarteritis nodosa, etc.—a less serious omission; since we are still not on sure ground in regarding these as examples of protein sensitization reactions, however suggestive one may think the evidence.

Asthma-Hay-fever-Urticaria Group

The first clinical observations linking asthma with sensitization were made by Hyde Salter, of London, and published in a monograph in 1860, "animal emanations" being blamed for the sufferings of many of his patients. Hay-fever had been accurately described some 30 to 40 years previously. In 1873 Blackley, a Manchester practitioner, published his *Experimental Researches on the Causes and Nature of Catarrhus Aestivus (Hay-fever or Hay-asthma)*, a book of such clarity and method that it should be studied to-day by anyone intending to work in this field. Like many others who have investigated this group of disorders, Blackley himself suffered with severe hay-fever. By testing his own skin he showed that reactions could be induced by some of the agents suspected of eliciting the symptoms in his nose and bronchi. He was thus able to examine current hypotheses, such as the causative effects of dust as such. Road dust from various sources rubbed into scarified skin produced no reaction, but pollen of certain kinds resulted within a few minutes in the now familiar sequence of events, with local swelling as a prominent feature.

*Lecture given to the Postgraduate Medical School and Institute of the British Postgraduate Medical Federation as part of the course on "The Scientific Basis of Medicine." Delivered at the London School of Hygiene on February 27, 1951.

Blackley's skin tests on himself might to-day be regarded as somewhat heroic in dosage, for he describes reactions lasting 24 hours or more, equalling an egg in size; at all events, he obtained results differing considerably from his controls. He was able in this way to define two basic facts about the tissue reactions to protein sensitization of the hay-fever type: (1) the reactions could be reproduced from a number of tissues—the skin of many areas, the conjunctiva, the linings of the nose and bronchi; (2) the reactions were narrowly specific. In his own case strongly positive results were given by the pollens of grasses and of another monocotyledon, the iris. Negative results were obtained with pollens from other (dicotyledonous) flowers. Even more striking examples of specificity have been given later, by examples such as that of a child sensitive to horses but able to ride a donkey in comfort. Blackley's hypotheses were naturally not all correct: obsessed somewhat with his own observations on grass pollens, he speculated about those patients suffering with asthma from animal emanations, pointing out that most of the animals concerned tended to be closely connected with hay—the kind of "association" pitfall which no doubt is trapping all of us to-day in other clinical ideas.

Nature of Skin Reactions

The nature of the skin reactions to protein substances causing asthma and hay-fever is now comparatively well understood. The local reddening and oedema with the surrounding flare—the triple response—were analysed by Sir Thomas Lewis (1927) in a familiar series of experiments of great beauty. The use of histamine to excite closely similar reactions led to the idea of a local release of a diffusible poison or H-substance, with effects limited to the blood vessels. Close comparison of the response to histamine and to protein antigens in suitable subjects by Hare (1926) showed that the two reactions were practically indistinguishable except perhaps for slight delay at the protein site. Similar local oedema and reddening occur in the conjunctiva and mucous membrane of the nose. By analogy with animal anaphylaxis, smooth-muscle contraction has been considered as an additional basis for the reactions of the bronchi in asthma, although it is not known certainly if this occurs in man.* d'Abreu (1940) has described an asthmatic reaction viewed through the bronchoscope: certainly, the reduction of the bronchial lumen was rapid and intense.

The local outpouring of secretions from nasal and bronchial mucous membrane in asthmatic and hay-fever attacks is not fully understood in terms of H-substance reactions. The two salient features of this type of reaction in any tissue are the rapid onset of oedema—within five minutes—and the minimal changes detectable by histological methods. Necrosis, for example, is never found even after considerable local dosage of sensitizing protein. Cellular infiltration, except on occasion for some local eosinophilia, is likewise absent.

The general rule that scientific observations and experiments in any field, initially qualitative, are found to be more rewarding when brought on to a quantitative basis can be illustrated here. If the ordinary prick test is performed with histamine as a test substance the errors of the method and the dose-response relationship can be worked out (Squire, 1950). Modern statisti-

cal techniques lighten the labour and extract the maximum information from the results. The prick test, carefully performed, can be shown to have a coefficient of variation (an "error") of not more than 20% for dosages resulting in wheal sizes of 1–6 mm. diameter, provided that standard and comparison tests are made on symmetrically placed sites, left and right, and within a short time of one another. Further errors are introduced if comparisons without standards are made on different days or on different sites (even, say, a few inches further down a forearm).

The diameter of the wheal responses is roughly proportional to the logarithm of the concentration of histamine (or of protein in a sensitive subject). In other words, if the wheal diameter is increased 1–1.5 mm. by raising the strength of the solution from 1:100,000 to 1:10,000 a similar further increase in size will be found by using a solution 10 times stronger still. The amount of solution introduced by a standard "prick"—forcible enough to cause momentary pain, but insufficient to draw blood—can be shown to be about 3 millionths of a millilitre.

From such quantitative considerations it can be shown that tissue reactions are produced by very small amounts of protein in asthmatic patients. A wheal 3 mm. across can be produced, for example, by as little as 10^{-13} g. of horse dandruff protein (probably as little as 10,000 molecules of protein). Similar responses in such a patient were only obtained with histamine solutions weight for weight 1,000 times stronger. As the molecular weight of the dandruff protein is probably 1,000 times as great as that of histamine, we must suppose (if histamine is indeed the reaction-mediating H-substance) that each molecule of dandruff protein introduced into the skin of certain asthmatics liberates (and that within half a minute) about one million molecules of histamine. This hypothesis perhaps needs re-examination. At all events, quantitative skin testing, with standard histamine to check the skin's reactivity and saline controls to avoid errors due to dermatographia, as well as with test protein solutions of known concentration suspected to be responsible for protein sensitization in any given patient, is still a rewarding field for further experiment.

Transfer of Sensitivity

Apart from specific reactions to certain foreign proteins widely disseminated through the body, the tissues of asthmatic patients show no obvious abnormality. Their skins are not, for example, in any way abnormally sensitive to histamine or to other known pharmacologically active bases. The serum or plasma of such patients is abnormal, however, in that, transferred to the body of a normal person, it induces exactly similar specific sensitivity. Clinical observations again gave the lead when Ramirez (1919) observed that blood transfusion from an asthmatic donor resulted in a sensitized recipient. Loveless (1941) made this the basis of experimental observations, showing that the induced sensitivity affected skin, conjunctiva, and mucous membranes, being fully established within 24 hours and lasting, though waning in degree, over periods as long as 30 days.

The local transfer of sensitivity to a small area of normal skin by means of an intradermal injection of, say, 0.05 ml. of asthmatic serum (Prausnitz-Küstner technique) has been widely used and is of practical and theoretical importance. The "antibody" from the

*But see Schild, H. O., Hawkins, D. F., Mongar, J. L., and Herxheimer, H., *Lancet*, 1951, 2, 376.

patient is to some extent "fixed" locally, for such a sensitized site is capable of reacting, even if testing is deferred for several days. In particular, this kind of experiment can serve as the basis of a quantitative assessment of sensitizing antibody circulating in the plasma of an asthmatic or hay-fever patient. For a sensitized site, having once given a full reaction, is "discharged" and cannot again be caused to react, even with much stronger test doses of sensitizing protein. This discharging reaction can be obtained either by pricking the sensitized site after, say, 24 hours, or by mixing sensitizing proteins in graded dilutions with the asthmatic serum before introducing it to the normal skin test sites.

If the minimal quantity of sensitizing protein required fully to discharge a site treated with a known quantity of asthmatic serum is regarded as an "equivalence dose" at least, comparative indications are obtained of the amounts of sensitizing antibody per millilitre of any patient's serum. Most immunological reactions—for example, precipitin reactions—involve not very dissimilar numbers of molecules of antigen and antibody. If these passive transfer reactions are assumed to follow a similar pattern, then it seems that quite small amounts of sensitizing antibody—for example, less than 1 mg./ml. of serum—are involved even in highly sensitized asthmatic patients.

Generalizations on Foreign Proteins

Turning to the foreign proteins responsible for tissue reactions in sensitization of the asthma-hay-fever type, certain tentative generalizations are now possible. Those adequately studied—for example, the proteins in grass pollen (Harley, 1937), ragweed pollen (Stull *et al.*, 1931), house-dust (Rimington *et al.*, 1947), and horse dandruff (Squire, 1950)—are all of the general nature of albumins. They are digested by pepsin in acid solution and lose their power to provoke reactions. They are precipitated from solution by saturation with ammonium sulphate, but not by half-saturation. My colleague, Mr. D. R. Stanworth, has been studying horse-dandruff albumin in parallel with recrystallized horse-serum albumin (both of these proteins often giving reactions in patients and

suitably immunized animals). The electrophoretic mobility of the main component of the unpurified dandruff albumin closely resembles that of serum albumin in barbitone buffer (see illustration). This general similarity between the proteins sensitizing man by inhalation as dusts is perhaps not extraordinary, being related probably to their molecular size. In general, very small molecules are not potent antigens, while large protein molecules withstand drying poorly, usually being denatured and rendered insoluble. Perhaps, too, large molecules would fail to penetrate the mucous membranes, and so never have an opportunity to sensitize anyone. Guesses of this kind may indicate why the proteins concerned are all found among the "medium-sized" proteins. There is no evidence that they are otherwise related, and they seem to vary considerably in chemical composition—for example, in combined carbohydrate content.

The proteins known to cause sensitization in man are fully antigenic in animals. Precipitins are formed in response to injection, and animals such as guinea-pigs become sensitive, developing anaphylaxis when re-exposed after suitable intervals. Sensitization and shock can be induced, as shown by Ratner (1939), by letting animals inhale a fine spray of dust of such proteins. Sensitization in man can be assumed to follow absorption of the proteins either by inhalation or by ingestion. Direct evidence is lacking, but previous exposure as a cause is strongly suggested by the absence of specific sensitivity (even when sought) in areas of the world which are free from some special protein—for example, that of ragweed pollen in Europe (see Cooke and Sherman, 1950). Normal persons can absorb proteins through the gut, intact enough at least to excite reactions in passively sensitized sites. Lewis used to describe an experiment which failed—but succeeded in a different sense. He had sensitized a site on his forearm with some serum from a fish-sensitive subject, intending to test some preparations of protein by pricking them into the site next day. On leaving his home in the morning, however, he felt his forearm itching, and realized that a reaction had occurred

Comparison between electrophoretic mobilities of horse-serum albumin and horse-dandruff proteins. (Barbitone buffer pH 8.6, $\tau/2 = 0.1$.) Note that main component of dandruff resembles serum albumin, but that a minor component of greater mobility is also present in dandruff. (Electrophoresis conducted by Mr. D. R. Stanworth.)

prematurely. Unthinkingly, Lewis had accepted and eaten a kipper served for his breakfast (see Lewis and Grant, 1926).

The riddle of asthma, then, is not so much, How can a patient have been sensitized? as, Why are we not all sensitized? Our food, the very air we breathe, is charged with proteins capable of sensitization, and normal individuals absorb these proteins, at least to some extent. True, hay-fever of mild degree is a very common disorder, but well-marked asthma due to protein sensitization in otherwise healthy young persons is not so common. The riddle of the familial tendency to develop sensitization of this degree is still unsolved. Perhaps it implies that intact proteins are more freely absorbed by subjects who are liable to sensitization, though so far no evidence in favour of this idea has been presented. The careful quantitative studies now being conducted in animals to establish the dosage-response relationships between foreign proteins and anaphylactic sensitivity (Kabat, 1947; Coulson and Stevens, 1949) may offer fresh clues and suggest new experiments to be conducted on suitable patients.

Blood Eosinophilia

A feature commonly found in patients of the asthma-hay-fever-urticaria group is a blood eosinophilia. Repeated injections of protein, though each may be temporarily followed by a drop in blood eosinophils, induces eosinophilia in animals (Biggart, 1932). Many observations, but comparatively few experiments, are reported which could help to establish the significance and function of the eosinophil cell. The asthmatic patient's sternal marrow may show slight evidence of increased eosinophil production. If such a patient is kept free from exposure to the proteins to which he is sensitive (for example, in hospital) a gradual decline, say from 600-700 to 300 eosinophils per c.mm., over a period of about six weeks occurs (unpublished observations on a single patient). Such studies have been made reasonably accurate by the direct counting methods of eosinophil cells (Discombe, 1946).

In man and in animals, sensitized tissues affected by exposure to the appropriate foreign proteins may become crowded with eosinophil cells some hours later. As a working hypothesis, the eosinophil cell may be regarded as being concerned with "mopping-up" the products of tissue damage. Certainly, the large granules, so refractile under dark-ground illumination, so dense under phase-contrast microscopy, have some very specific function. In thin films of blood examined when warm and fresh the eosinophil is just about as active as a neutrophil polymorph leucocyte, moving with all its granules (except one or two) foremost. Phagocytosis of cocci by eosinophils is not readily observed in contrast with the behaviour of the polymorph. But the eosinophils will adhere to wettable surfaces, and on occasion—when offered, for instance, clumps of dead tubercle bacilli—they will lie close with only the granules in movement, circulating internally as if allowing different granules a period of active absorption close to the cell surface followed by a period of recovery deep in the cell body.

Are the granules acid (and avid for eosin) and capable of adsorbing base? Apparently, disruption of the eosinophil is the main source of histamine from the cells of the blood (Code, 1937). We are close to confusing fact and hypothesis in this account, but at least it can be said that the eosinophil cell is worthy of

greater attention. Easily distinguished and handled as a living cell, its granules appear intact if the cell is disrupted by pressure—they could be separated and analysed.

Tuberculin-Trichophyton Group

The reactions to tuberculin have occupied the attention of physicians ever since Koch (1890) made the unfortunate claim for this substance as a remedy for tuberculosis. It is now clear that sensitization closely analogous to that which follows infection with tubercle bacilli may occur with other infections—for example, by species of the fungus *Trichophyton*, as in athlete's foot. As the details of tuberculin sensitization have been more fully studied, it seems best to concentrate upon these reactions which serve as a type for the whole group. Much space in Arnold Rich's (1944) absorbing book is given over to describing the facts of sensitization. Here only the salient features can be mentioned, with particular stress on the similarities and differences between asthma-type and tuberculin-type sensitizations.

The quality of specificity of the tuberculin reaction is just as striking as that of the asthma-hay-fever group. In fact, the practical application of this form of sensitization at present is in diagnostic tests, which determine whether or not an individual has been infected with tuberculosis. Just as in hay-fever the skin can be shown to be sensitive to many species of grass, so in patients infected with either human or bovine strains of bacilli skin reactions to any tuberculin can be demonstrated. Unrelated infections, however, as with *Trichophyton*, confer sensitization specifically, to, say, trichophyton, and not at all to tuberculin.

Sensitization of the tuberculin type can be shown to be widespread throughout the body, to a greater extent even than in asthma-type sensitization. Lung, kidney, testes, meninges, cornea—all show evidence of sensitization when tested experimentally (see Rich, 1944). The skin has been studied most, as it is most easily observed. When compared with the wheal-reaction characteristic of asthma-type skin tests, the tuberculin reaction differs profoundly even on naked-eye observation. Most striking is the difference in time relations. The mild asthma-type reaction appears in a matter of minutes and fades in half an hour. The tuberculin reaction may just be evident some eight hours after the introduction of the test solution, is at its height after 24 hours, and disappears only after some two to three days. Even then signs of the reaction may persist in the form of slight pigmentation and some flaking of the epidermis, for lasting cytological changes are present in the dermis. Overdosage with tuberculin causes local necrosis, never seen with the skin tests for asthma. Systemic reactions, too, may occur, but again these differ from those following overdosage with the agents which elicit asthma and urticaria, by being slower in onset and more long-lasting, with fever and a general bodily disturbance.

Dosage-response relationships have been worked out with tuberculin as with asthma-type reactions (Wadley, 1949; Long and Miles, 1950). A convenient index of reaction strength is again the diameter of the local oedematous area, but in this case measured after 24 hours rather than after 10-15 minutes. The diameter of the local lesion is also proportional over a fair range to the logarithm of the dose of tuberculin introduced.

Histological Changes

The histological changes accompanying the tuberculin reaction have been described and debated in detail. There can be no doubt about the striking degree of these changes, in contrast with the asthma-type reactions, nor about the extensive cellular infiltration with the various types of wandering cell, including polymorphs and mononuclears, as seen in many kinds of inflammation. Histological examination of lesions in this case more delicate than clinical observation, in the sense that changes can be seen in sections of skin removed from tuberculin-test sites before the reactions are visible to the naked eye.

The observation that wandering cells participate in these reactions falls into line with the later experimental findings that tuberculin sensitivity can be passively transferred from one individual to another, not as in the Prausnitz-Küstner technique by serum, but only by the transfer of cells (leucocytes). This striking advance was achieved by Chase in 1945. Guinea-pigs were artificially sensitized by injection of tubercle bacilli. When concentrated suspensions of their leucocytes (0.2 ml.) were introduced into normal animals by intravenous or intraperitoneal injection the recipients were clearly sensitized as judged by tuberculin skin-testing, albeit for a few days only. These experiments have been amply confirmed by other workers in the United States, and extended by the work of Lawrence (1949), who showed that more striking degrees of sensitization can be induced in man. Lawrence used relatively smaller dosages of leucocytes, but the human cell donors were probably more highly sensitive than Chase's animals, being selected from patients naturally infected with tuberculosis. The tuberculin-negative recipients were injected intradermally. Sensitization then spread in many instances to involve even remote skin sites, and lasted sometimes for a month or two as judged by the usual intradermal tuberculin tests.

The importance of the motile cells in tuberculin sensitization is also underlined by tissue-culture experiments. The experiments of Rich and Lewis reported in 1932 can justly be described as classical, if not on grounds of antiquity then on the basis of their elegance. In suitable concentrations tuberculin gave no appreciable effect when added to cells grown from tissues of normal guinea-pigs, even if serum from sensitive animals was also added. But cells from guinea-pigs previously sensitized, even when washed and cultured in normal guinea-pig serum, were damaged by similar concentrations of tuberculin. Fibroblasts perhaps were relatively unharmed, but wandering mononuclears migrating out in tissue culture were slowed down, stopped, and eventually killed. Recently, Cruickshank (1951) has extended the idea that not all types of cell from sensitized animals are susceptible to tuberculin, by showing that sensitized guinea-pig epidermis can grow in media containing concentrations of tuberculin considerably above those required to excite gross reactions in the skin of the intact donor animal.

The generalization that tuberculin sensitivity is not dependent upon a serum factor is not disturbed by the experiments of Miller and Favour (1951). These workers have demonstrated that further complexities may be found in the serum of patients in certain stages of tuberculosis, as judged by acute behaviour changes in various blood leucocytes when acted upon by serum-tuberculin mixtures (Favour *et al.*, 1949).

Whereas a special study of the eosinophil leucocyte is needed to increase our knowledge of the asthma-urticaria type of sensitization, with regard to the tuberculin-trichophytin reactions the focus narrows on to the lymphocyte—or at least to the various types of mononuclear cell. These cells are very active in tissues, wandering rapidly from site to site, as described by Ebert *et al.* (1940) in the rabbit's ear.

The chemical eliciting the tuberculin reaction is undoubtedly protein in nature. The work of Seibert (1944) and others has shown that activity can be demonstrated in proteins of various sizes, but that the most highly active material, now usually known as P.P.D. (purified protein derivative) has a molecular weight of about 35,000, and is homogeneous in electrophoretic experiments. The material of lower molecular weight found in old tuberculin is presumably derived from P.P.D. by breakdown. But none of these protein fractions, injected alone by any route, has been shown to cause the development of tuberculin sensitization—another point of major difference from the anaphylactic form of sensitization. But even dead tubercle bacilli, injected in sufficient quantities, readily induce sensitization in suitable animals, such as rabbits and guinea-pigs. It has now been shown that the essential difference between the bacillus and the protein derived from it depends upon the presence of specific materials (perhaps capable of inducing phagocytosis by mononuclear cells), since suitable mixtures of tuberculoprotein with the wax of the tubercle bacillus injected into guinea-pigs have proved capable of inducing specific tuberculin-type sensitivity (see Raffel, 1948). Much remains to be discovered about the differing forms and degrees of sensitization which follow inoculations by different routes and in different mixtures with poorly soluble materials, though striking progress has recently been made, most clearly described (at the same time with a suitable sense of excitement) by Burnet and Fenner (1949).

Control of Sensitivity Reactions

The medical scientist is sometimes, not unjustly, accused of being less interested in the treatment of disease than in the original condition and its basis. This should not be so; not only does the understanding of disease mechanisms suggest rational lines of treatment, but the success or failure of therapy, rational or empirical, may often be used to validate or disprove current theories about the nature of a disease. From this point of view, three methods now in use for controlling the reactions to sensitization merit discussion—"desensitization," the "antihistamine" drugs, and cortisone.

Desensitization

This term was used to describe the effects of sublethal anaphylactic shock in experimental animals. After administration of suitable doses of specific protein, further injections may be without effect or may produce only minor reactions. This state of reduced reactivity, however, lasts only a few days at most; the only parallel in human medicine is probably found in such circumstances as when a horse-sensitive subject is treated with increasing doses of horse serum (starting with very small amounts) during a period of hours, so as to enable an adequate dose of some vitally needed antiserum to be administered. As in the animal, this desensitization is of limited duration.

On the other hand, a course of injections of, say, pollen extracts given to a patient regularly attacked by summer hay-fever, in increasing dosage at intervals of three to seven days, is well known to induce in a fair proportion of instances a gradual lessening of reactivity of skin and other sites to pollen tests and of the symptoms and signs of attacks. Several months of treatment are usually required, and the beneficial results may not last for more than one season.

The confusion of thought resulting from the use of the same word "desensitization" to describe these events, has been unfortunate. The procedure required clearly suggests that some form of immunization process is involved, and experiments with the serum from patients treated in this way has confirmed the presence of a neutralizing antibody capable of combining specifically with the pollen protein in such a way that it no longer elicits skin reactions (Loveless, 1940; Harley, 1942). Simple tests—for example, stability to heat—can be used to differentiate this neutralizing antibody from the sensitizing substance originally present in the hay-fever subject's serum. These important findings deserve further work, directed, in particular, towards easier methods of determining *in vitro* the concentration of neutralizing antibody achieved at various stages of this form of treatment. The gradual reduction of tuberculin sensitivity which can be achieved by successive injections of the appropriate protein has not, apparently, been tested to determine whether a similar or different mechanism is involved.

Antihistamine Drugs

These were originally discovered by Bovet and Staub (1937) in Paris. Halpern (1950) has reviewed his own and other contributions to the introduction of compounds suitable for human administration, and has summarized recent experimental work. The antihistamine drugs are usually strikingly effective in controlling urticaria and hay-fever. Caution must be exercised, however, in drawing conclusions from this finding, since only some of these drugs single out histamine for antagonism (see Gaddum, 1948). Quantitative skin-testing shows that a great reduction occurs in the wheal-like responses to specific protein inoculation. Guinea-pig lung reactions to histamine, and (in sensitized animals) to doses of protein considerably greater than those known to cause death in unprotected animals, are abolished. In man, control of asthma is less certain; in some trials the patients' reports of improvement may have been vitiated by insufficient control of the "suggestion" factor—for example, failure to use dummy tablets—in others, the selection of patients has not been such as to ensure that true examples of sensitization were being studied. Whereas the asthma-urticaria group of patients are usually benefited by treatment with the antihistamine drugs, the sensitivity reactions of the tuberculin-trichophyton group are unaffected.

Cortisone

The effects of cortisone and of cortisone-liberating A.C.T.H. have been studied for too short a time for the formulation of more than tentative conclusions. It seems generally agreed at present that these drugs greatly diminish the naked-eye reactions to tuberculin, but have negligible effect on the wheal-like reactions to histamine or to agents such as pollen concerned with the asthma-urticaria type of response. It is clearly of very great importance to study the nature of this inhibition of

the tuberculin reaction. A local effect of cortisone on ground-substance of subcutaneous tissue can be demonstrated by measuring dye-spreading round the site of injection (Gell and Hinde, personal communication). Histological studies of tuberculin reactions at various stages in their development in the rabbit have shown a highly significant reduction in the proportion of mononuclear cells as compared with polymorphonuclear leucocytes (Gell and Hinde). Whether these and the various other known effects of these hormones can eventually be correlated into a simple picture is uncertain at present: in their effects on the tuberculin reaction, at least, it seems that once again the behaviour of the mononuclear wandering cell is of major importance.

Conclusions

The study of sensitization often seems to raise as many questions as answers—a sign, perhaps, of a field of investigation worthy of further cultivation. In the introduction to this paper the importance of hypotheses in the advancement of medical science was explained, with the suggestion that a sign of merit was current usefulness rather than a pretence of final truth. With this justification an outline may be given of some working hypotheses designed to stimulate experiments on sensitization.

The asthma-urticaria type of reaction is evoked in certain tissues by the combination of a specific antibody, which is derived from the patient's plasma globulin, with appropriate antigens. These antigens are proteins encountered in the natural environment, are of medium molecular size, are usually relatively stable to drying, and have presumably induced sensitization on some previous occasions when inhaled or ingested by the patient. The reactions in various tissues responsible for the symptoms and signs are mediated by the release of pharmacologically active substances, among which a base having histamine-like properties is prominent; subsequent neutralization of reaction products may be carried out by eosinophil leucocytes. Parenteral administration of the same antigen (though usually in amounts differing considerably from those absorbed under natural circumstances) can give rise to the formation of neutralizing antibodies which may reduce the degree of reaction to subsequent exposure.

Tuberculin-trichophyton type sensitization follows phagocytosis of certain forms of poorly soluble material—for example, wax—along with specific proteins derived from various micro-organisms. These phagocytes and similar wandering cells may then carry sensitivity widely through the body. On subsequent contact with specific protein—for example, tuberculin—these mononuclear cells react by releasing substances capable of dilating small blood vessels and attracting other mononuclear cells to the vicinity. Enzyme liberation may also occur, perhaps tending to digest the foreign protein and even, in sufficient concentrations, to affect also the local tissues and ground-substance. The functional activity of these mononuclear cells is controlled by circulating hormones—for example, cortisone and thyroxine.

Caution would have dictated the use of "perhaps" many times in these two paragraphs. The techniques, however, for proof or disproof are ready to hand, and hypotheses should not expect a long life. Heparinized blood can be separated by red-cell aggregation with dextran or fibrinogen; the supernatant, rich in white

cells, can be poured through glass wool, to which the polymorphs adhere. The filtrate has only to be lightly centrifuged to obtain lymphocytes—alive if suitably handled. Do these cells carry the essential properties required by the hypotheses? If so, under what circumstances? Similarly, many more experiments need to be performed before the explanation of the various types of "antibody" found in asthma can be regarded as "being on a scientific basis."

Summary

Protein sensitization in man is a suitable subject for scientific study, especially when reinforced by animal experiments. Two main types—the asthma-urticaria and the tuberculin-trichophyton type—are considered and contrasted. Some of the methods of controlling sensitization reactions are discussed. Tentative hypotheses suggesting further experimental work are outlined.

The annual report of the honorary secretary of the Joint Tuberculosis Council briefly records the work of the council during the year. Probably the most important achievement was the completion and publication of forms of record for use in chest clinics. At the request of the Ministry of Health the council drew up a memorandum on the internal administration of hospitals, and members of the council also assisted the Ministry in drawing up a report on skiagraphic terminology and radiographic technique. A trial of a four-digit classification of tuberculosis was undertaken at the request of the World Health Organization.

DENTAL DISEASE AMONG 14-YEAR-OLD LONDON SCHOOL-CHILDREN IN 1947 AND 1950

BY

MAY MELLANBY

AND

HELEN MELLANBY, M.D., Ph.D.

with the assistance of

JOAN JOYNER, B.Sc., and MARION KELLEY
 (From the Nutrition Building, National Institute for Medical Research, Mill Hill, London)

The Education Act of 1944, which raised the school-leaving age to 15, gave the opportunity for making dental surveys of the 14-year-old group. This age is suitable for the examination of the permanent teeth, as most types have erupted, with the exception of the third molars, while few deciduous teeth remain to be shed. It also provides an overall picture of the state of dental fitness of a section of children the majority of whom are about to leave school, and as such it will no doubt be of interest to the public health authorities.

The two surveys with which this paper is concerned were carried out during the winter months of 1947-8 and 1950-1, but for the sake of brevity they will be referred to as the 1947 and 1950 surveys. The London County Council very kindly afforded facilities for making the inspections, all of which took place in schools under their authority, the number of children examined being 1,216 in the earlier year and 1,089 in the later. These children were unselected samples distributed between modern, technical, and grammar secondary schools, the proportions from each bearing a rough relation to that of the total child population attending the different kinds of secondary schools in the area. In both surveys approximately 72% were from the modern schools, 12% from technical schools, and 16% from grammar schools. Since more children attend modern schools, any differences between the teeth of these children in the two surveys have more influence on the total figures than have the differences between the teeth of technical or grammar pupils. The samples of children from the latter kinds of school were too small to give more than an indication of possible differences between them and the moderns, especially where individual types of teeth are concerned.

The examination procedure and the charts used for recording the dental condition of the children were basically the same as those employed in the surveys of 5-year-olds from 1943 onwards (see Mellanby and Coumoulos, 1946), but certain adaptations were made to suit the charts for use with the permanent dentition (see Chart). Although external structure (as gauged by M. Mellanby's probe method), the incidence and extent of caries, mottling of the enamel, tartar, gingivitis, alignment, and occlusion were recorded, in the present paper only the results relating to the incidence and extent of caries, gingivitis, and tartar are given.

Methods

Each child's mouth was carefully examined by one of us with a standard probe and illuminated mirror, the results for each individual being separately charted.

Tartar deposits on individual teeth were graded on the charts as 1, 2, or 3, according to whether they covered up to one-third, two-thirds, or the whole of the buccal or lingual surface. From these figures an average assessment for each mouth was obtained, and the children were then graded into four categories—0, 1, 2, and 3.

Caries

The number of children examined in the two surveys and distributed between the three kinds of secondary school are given in Table I, column 2. The totals for

1950 were rather fewer, but the proportions attending the modern, technical, and grammar schools were the same on each occasion. In the 1947 survey 54% of the children were boys and 46% were girls, whereas in 1950 the respective percentages were 55.8 and 44.2, the average age on both occasions being 14 years 5 months.

The proportion of children considered to be caries-free, according to the standards used, increased from 11.5% in 1947 to 16.1% in 1950 (Table I, column 3). This increase was spread over the three kinds of school, being more pronounced in the modern than in the others. The total percentage of children with very little decay (Table I, column 4) also increased, but this was entirely because the considerable improvement in the modern pupils more than compensated for the reduced number of such children in technical and grammar schools. The average number of carious teeth per child (equivalent to the D.M.F. per child of some authors) showed a slight overall reduction, which was again achieved by the modern schools' improvement exceeding the somewhat worsened state of affairs in the others. More boys than girls were found to be caries-free in 1950—about 19% as compared with 12%—whereas in 1947 the difference in this respect was negligible.

In Table II an attempt has been made to gather together from the literature a few comparative caries figures for other groups, mostly children of fairly similar age who had also been examined with a probe and mirror. From this table it will be seen that in some communities, such as Hagerstown (U.S.A.) and Newfoundland, caries incidence was high, only 4.6 and 0.8% respectively of the children examined being caries-free at 14 years of age. Children from Chicago, Trinidad, and American Indian reserves gave intermediate figures of 14.4, 13.8, and 23% respectively of individuals caries-free. Where caries incidence in this age group was considered to be comparatively low, as in the Isle of Lewis, Scotland, the town of South Shields, England, and Northern Italy, the percentages of caries-free children were 30.8, 25.8–50.6, and 38.4 respectively. African and, more recently, Indian children were found by M. Mellanby to be remarkably free from caries; in the latter case 65.8% of the 14-year age group at Lucknow were in this category. From these figures it will be realized that the London children in 1950, with 16.1% of individuals free from decay, were better than some groups, though a long way from the best so far reported, even for this country—for example, Lewis and South Shields.

The percentage of teeth present in the London children at the time of inspection are given in Table III. These figures represent the teeth actually seen in the mouth (extractions as well as unerupted teeth being omitted here), as compared with the possible total if every child had 28 permanent teeth erupted. The very few third molars observed were excluded. The majority of the 28 teeth per child were *in situ*, the percentages being 94.8 in 1947 and 95.9 in 1950.

Individual differences in the proportion of the various types of teeth present in pupils from the three kinds of school were on the whole very small. In 1947 the percentages of upper and lower first molars were highest in the grammar schools and lowest in the modern, the difference being between 6 and 7%. In 1950 there was no difference between the schools as regards upper first molars, but of the lower first molars the grammar schools now had the lowest percentage and the technical the highest, the discrepancy between them being 6.8%.

A proportion of the spaces for unerupted permanent teeth were still occupied by deciduous predecessors; for example, in 1950 there were 139 deciduous teeth still retained, of which 33.1% were upper canines and 57.6% were second molars. No records were made of

decay in these teeth, all the figures for caries incidence and extent given in this paper referring to the permanent dentition only.

An analysis of the caries results for both surveys and for each type of permanent tooth in the combined schools is given in Table IV. Column 2, compiled from the numbers of teeth inspected plus those extracted for caries, shows the total numbers on which the analysis is based. As is usual in most civilized communities, the tooth most frequently attacked by disease was the lower first molar (over 60% in each survey being carious), with the upper first molar coming next. The least attacked were the canines, the lower incisors, and the lower first premolars.

The caries incidence for all types of teeth together was 14.6% in 1947 and 13.9% in 1950 (Table IV, column 7). When the different types of teeth are considered individually, however, it will be seen that there was more caries in 1950 among the upper incisors and rather less in the first molars. The A.C.F. for these teeth (column 8) showed corresponding increases in the upper incisors and decreases in the first molars. The very slight overall improvement in the caries position in 1950 compared with 1947, therefore, was not achieved by a uniform reduction of decay, but rather by the reduction in the incidence of first molar decay exceeding the increase experienced in the upper incisors.

The caries incidence and extent in the three varieties of school are set out in Table V. From the total percentages at the bottom of column 7 it will be seen that in 1947 the technical schools had the lowest overall caries incidence and the modern schools the highest, though the difference between them was very small (13.7% compared with 14.8% of teeth affected). By 1950 there had been a slight reduction of caries in the modern schools (from 14.8 to 13.4%), whereas in the other two groups the incidence had apparently increased a little (from 13.7 to 14.8% in the technical schools and from 14.5 to 15.4% in the grammar schools), though as the samples were small too much importance should not be attached to individual results for technical and grammar schools. It will also be seen from Table V, column 7, that the improvement in the caries position

TABLE III.—Percentage of Permanent Teeth of Each Type In Situ

* A.C.F. (average caries figure) = $\frac{\text{Total caries figure}}{\text{Total number of teeth, including extractions}} = \frac{\text{No. of } C_1 + 2(\text{No. of } C_2) + 3(\text{No. of } C_3)}{\text{Total number of teeth, including extractions}}$

of the modern schools in 1950 was largely attributable to the marked reduction in the caries incidence in the first molars, whereas in the other varieties of school there was an increased incidence in these teeth. The upper incisors showed more decay in all three kinds of school in 1950, but it was greater in the technical and grammar than in the modern schools. These differences are also seen in the average caries figures (column 8). The greatest discrepancies between the schools in the respective surveys occurred in the lower second molars in 1947 and in the upper and lower first molars in 1950.

When the percentage of carious teeth found in the London children in 1947 and 1950—namely, 14.6 and

13.9—are compared with the findings in other groups in various parts of the world (see Table II), it will be seen that the London children occupy an intermediate position. They have less decay than West Indian, Newfoundland, and some U.S.A. children, but more than children from Lewis (Scotland), and many more than groups of Africans and Indians.

Table VI, which indicates the amount of dental treatment given to the London children, shows that approximately the same percentage of carious teeth had been extracted in the case of the children examined in the two surveys—12.3 in 1947 and 11.5 in 1950—while there was a slight falling-off in the percentage of carious

* In a few instances gingivitis and tartar figures on the charts were found to be incomplete; these charts were therefore excluded in preparing Tables VII and VIII.

teeth which had been filled—43.6 in 1947 compared with 39.3 in 1950. There was therefore an overall reduction of 5% in the proportion of carious teeth treated as between the 1947 and 1950 surveys. A comparison of the figures for the three kinds of school shows that technical and grammar schools had had some increase in treatment. It was in the modern schools where this had been reduced, but it will be noted that it was the children in these same schools who showed a reduction in caries incidence (see Table V). A small amount of apparently "arrested" caries was found in the two surveys. This occurred in 3.69% of all untreated carious teeth in 1947 and 2.66% in 1950 (see Table VI, column 5).

Gingivitis and Tartar

The results of the gingivitis estimations based on the criteria described above are given in Table VII. Here it will be seen that only 26.3% of the children in 1947 and 14.9% in 1950 were considered to have no gingivitis, approximately two-thirds in both years had a slight or moderate degree, while relatively few, 9.3 and 7% respectively, were counted as having a severe type. It would therefore appear that gingivitis was a common condition among these children, and that its incidence had apparently increased between 1947 and 1950.

A few comparative figures for other surveys are also given in Table VII, showing that gingivitis, at least in a mild form, is widespread, though its occurrence seems to have no simple explanation. It is always difficult to compare the findings for the incidence and degree of gingivitis of different workers, since the standards vary, quite apart from personal factors in the examinations. For this reason the investigations to which reference is made here are confined to those of ourselves and a former colleague, J. D. King, who has latterly made an experimental and clinical study of the subject. He employs a more detailed classification than we, so that his results for the West Indian children in Trinidad and British Guiana are not strictly comparable with our findings in London, Newfoundland, and India.

Table VIII (column 2) gives the number of London children with various grades of tartar deposition from 0 to 3 (see above), from which may be calculated the incidence of the different degrees and the average tartar figures. The same table (columns 3 and 4) also gives the associated occurrence and extent of gingivitis. The areas of the mouth most commonly affected by tartar were, as is usual, the upper first molar and the lower incisor regions. Some 5% fewer children were free from tartar in 1950 as compared with 1947, but 7% more had only a slight degree; the average tartar figures (calculated on the same basis as the average caries figures) will be found to be almost identical for the two surveys.

Although many of the children with no tartar had gingivitis, this was generally of a milder degree than that experienced by children having calculus. With increasing amounts of tartar the incidence of gingivitis was also raised, until with extensive deposits (grade 3) 94.6 and 97.7% respectively of the children in the two surveys had some degree of parodontal abnormality (Table VIII, column 3). The average gingivitis figure also increased considerably with moderate and extensive amounts of tartar (Table VIII, column 4). In the Trinidad and Jamaican children examined by King a high degree of association was found to exist between gingivitis and tartar deposition when the location of the two was restricted to the anterior part of the mandible (King and Martin, 1951).

Conclusions

On the whole we were favourably impressed by the state of these 14-year-old children's teeth. They were better than we had anticipated, especially when allowance was made for all the difficulties of the present time. Any differences between the overall caries incidence in the teeth examined in the two surveys were slight, but some shift of caries away from the first molars was discernible, and with this went an increase in the disease among other teeth, especially the upper incisors. Both surveys showed a high incidence of gingivitis, but there was appreciably more in 1950 than in 1947, and also slightly more tartar.

Summary

Two surveys of 14-year-old London County Council school-children from modern, technical, and grammar schools provide the clinical material for this paper. The inspections were made with a probe and mirror.

The proportion of children found to be free from caries, according to the standards used, was 11.5% in 1947 and 16.1% in 1950. These results are compared with figures from different parts of the world, including other areas of Britain.

A detailed analysis of the incidence and extent of caries in the different types of teeth is given for all the schools

TABLE VIII.—The Association Between Tartar Deposits and the Occurrence of Gingivitis

Grade of Tartar	No. of Children		Percentage of Children with Gingivitis		Average Gingivitis Figure	
	1947	1950	1947	1950	1947	1950
0	469	368	65.5	81.7	0.99	1.24
1 (slight)	364	400	71.2	85.5	1.17	1.34
2 (moderate)	285	259	84.9	87.3	1.59	1.54
3 (extensive)	74	44	94.6	97.7	2.14	2.00
	1,192	1,069	73.7	85.1	1.26	1.38

taken together in the two surveys. A separate analysis for the three kinds of school is also given, but with few exceptions the differences between them were not large. A total of 14.6% of the teeth in 1947 were carious, whereas for 1950 the figure was 13.9%. Comparative figures for caries incidence in other groups of children are given.

Only small differences were found between the two surveys as regards the amount of caries in the different types of teeth, but in 1950 more upper incisors and fewer first molars were carious than in the first survey.

The amount of treatment (fillings and extractions) which the teeth had received is briefly considered. An overall reduction of 5% was noted in 1950 as compared with 1947.

Some degree of gingivitis was found to occur in 73.7% of the children examined in 1947 and in 85.1% of those seen in 1950. That this is a common finding in this age group is substantiated by figures for other surveys.

Tartar deposits were frequently found, and there appeared to be some relation between the amount of tartar and the incidence and extent of gingivitis.

We wish to thank the London County Council and Sir Allen Daley for permission to carry out the inspections, and we are much indebted to the head teachers and staffs of the schools for all the help they gave with the actual examinations. Our thanks are also due to Miss I. Allen, of the Medical Research Council's Statistical Department, for advice, and to the Medical Research Council for financing the work.

INTESTINAL MACROCYTIC ANAEMIA

BY

G. M. WATSON, D.Ph., M.B., B.S., M.R.C.P.*

AND

L. J. WITTS, M.D., F.R.C.P.

(From the Nuffield Department of Clinical Medicine,
the Radcliffe Infirmary, Oxford)

The occasional association of pernicious anaemia with intestinal stricture was discovered by Faber in 1895. In the succeeding years more cases were recorded, and in 1924 Seyderhelm and his associates claimed to have reproduced the syndrome in dogs. In 1929 Little, Zerkas, and Trusler found a blood picture typical of pernicious anaemia in a young man on whom several operations had been performed to cure an intestinal fistula which followed acute appendicitis. This appears to be the first record of pernicious anaemia in association with intestinal anastomosis as distinct from stricture. Other cases of this kind have since been reported, and the lesion has usually been either a gastro-jejuno-colic fistula or a stagnant loop of intestine. Tönnis *et al.* (1932) reported a brilliant series of experiments on culs-de-sac of the small intestine in dogs, and showed that the anaemia which sometimes developed would respond to liver extract.

In 1939 Barker and Hummel reviewed 51 cases of human pernicious anaemia associated with intestinal stricture or anastomosis, and we later brought the total to 60 (Cameron, Watson, and Wits, 1949a). In these 60 case reports anastomosis was the basic abnormality in 23, while in 37 one or more strictures were present. The strictures were mostly of the small intestine, but six were in the colon. Of the anastomoses 14 were entero-enterostomies or entero-colostomies, and nine were gastro-colic or high jejuno-colic fistulae.

The syndrome of gastro-colic fistula is now well known, its principle features being diarrhoea, steatorrhoea, malnutrition, and anaemia. Renshaw and his co-workers (1946) have made a careful clinical and experimental study of this condition. Dogs in which a gastro-colic fistula was made by operation developed a syndrome similar to that seen in man, including anaemia which in some cases became macrocytic and hyperchromic. In the dogs and in human cases it could be shown that there was little passage of gastric contents to the large bowel, and consequently the symptoms could not simply be due to diversion of food from the small intestine; rather were they due to contamination of the stomach and small intestine by colonic matter. In the cases of anaemia associated with stricture or anastomosis the fundamental abnormality appears to be the presence of a stagnant or obstructed portion of small intestine. All these mechanisms may lead to infection of the small intestine with colonic organisms.

Prominent Features

The salient features of pernicious anaemia in association with intestinal stenosis or anastomosis can be briefly enumerated. The tongue is often sore, but there is free acid in the gastric juice in more than half the cases. Intrinsic factor has been demonstrated in one case (Schlesinger, 1933), although it was absent in the only other case in which it was looked for (Castle *et al.*, 1931). Steatorrhoea is not necessarily present, but there have been few careful observations on the fat excretion. Subacute combined degeneration occurs in a fairly large proportion of cases. The bone marrow is megaloblastic, and the anaemia, which is macrocytic, responds to treatment with liver, though it is sometimes rather resistant. No information is available about the response to vitamin B₁₂, folic acid, or antibiotics. The anaemia may be permanently cured by surgical correction of the intestinal abnormality, though this cannot be promised with certainty. The syndrome has declined in frequency in recent years owing to the decreased incidence of intestinal tuberculosis, which has been the most frequent cause of stenosis of the small intestine, and to technical improvements in surgery, which avoid the formation of stagnant loops of intestine.

Present Investigation

The essential feature in macrocytic anaemia of intestinal origin appears to be stagnation, whether from stenosis or in a stagnant loop. The syndrome differs from Addisonian pernicious anaemia in that the secretion of hydrochloric acid and intrinsic factor by the stomach may be normal; and from sprue in that there need be no steatorrhoea. It seems particularly appropriate for experimental study because it is impossible to produce a megalocytic anaemia by operations on the stomach in animals (Cameron, Watson, and Wits, 1949b), and

*Australian National University Research Fellow.

pernicious anaemia does not always develop after total resection of the stomach in man (MacDonald *et al.*, 1947).

These observations led us to the working hypothesis that in pernicious anaemia the failure of gastric secretion might merely set the stage for the development of anaemia, which was actually initiated by events in the small intestine. With this idea we began a series of experiments with rats. We considered that the disadvantage of using so small an animal was outweighed by the ease with which we could make large numbers of preparations. A further point is that the diet and digestive tract resemble that of man, and we have been able to prepare extracts from rat livers which are effective in human pernicious anaemia. Adult albino rats of the Wistar strain, aged 4 to 6 months, have been used in all experiments. They have been fed on a synthetic diet (Watson, Cameron, and Witts, 1948), but anaemia will develop in animals receiving a mixed diet with plenty of animal protein (W. A. Broom, J. Emmet, and Woods, 1949, personal communication).

Experimental Technique

The initial experiments were designed to produce intestinal stricture and chronic obstruction, but although several methods were tried none was found satisfactory. The next procedure was to divide the small intestine at the junction of its upper and middle thirds and implant the lower end of the upper intestine into the side of the small intestine at the junction of the middle and lower thirds; in this way the middle third of the small intestine is by-passed. This operation is relatively easy to perform. Nearly 200 rats were prepared in this way, but only about 10% of them developed a macrocytic anaemia, and the proportion tended to lessen as the operators became more skilled. These experiments confirmed the results of other workers who had found that a large proportion of the small intestine can be removed or by-passed without anaemia resulting, and indeed the majority of the rats lived to a ripe old age. More important was the discovery that in rats which developed anaemia there was always some dilatation of the blind loop. In most cases this was limited to the proximal 6-10 cm. of the loop and the anastomotic area, but in a few there was also some dilatation of the small intestine above the anastomosis.

The Blind-loop Operation

If was therefore decided to reverse the direction of the blind loop so that now peristalsis would tend to fill instead of emptying it. This was done by dividing the small intestine at the junction of the middle and lower thirds, and anastomosing the lower portion to the side of the small intestine at the junction of its upper and middle thirds. The same segment of intestine was by-passed as in the earlier operation, but the effects were very different. The operation was technically more hazardous because peristalsis now tended to break down the anastomosis. The middle third of small intestine, approximately 12 in. (30 cm.) long, increased in diameter and formed an easily palpable tumour. Three out of every four rats died within three weeks, but all those which survived for that time developed macrocytic anaemia.

Further experiment showed that the percentage of anaemic animals, the speed of onset of the anaemia, and the mortality of the operation were all directly proportional to the length of the loop. It was then a straight-

forward procedure to work out the optimum length and position of the loop. As a result of these studies all our subsequent work has been done with 3 to 4-in. (7.5 to 10-cm.) self-filling loops placed not lower than the middle of the small intestine. Culs-de-sac from the lower

Operative Mortality and Incidence of Anaemia

Death within one month of operation ..	51.7%
Dying up to six months from later complications or -	
unknown causes ..	21.6%
Surviving six months or more without anaemia ..	7.4%
Developing anaemia ..	19.1%

Deaths within the first month were mostly from leakage or obstruction. Obstruction or perforation still occurred frequently in the later period, but many rats died without the cause being apparent at necropsy.

ileum usually fail to produce anaemia. The Table shows the overall operative and post-operative mortality of rats prepared by this final operation. It is necessary to point out that the incidence of anaemia varied considerably, at different periods for no very obvious reason. Thus, in one set of experiments a yield of only a little over 10% of anaemic rats was obtained, while in another it was as high as 42%.

Post-mortem Findings

At post-mortem examination of animals which have survived the immediate hazards of operation the wall of the cul-de-sac is dilated and hypertrophied, but there is no inflammation or ulceration save in the exceptional case in which rupture has occurred. The tongue, stomach, and the rest of the gut appear normal, as do the other viscera. Histological examination of all these structures shows no departure from the normal. There is some haemosiderosis of the spleen, but the liver and kidneys are normal. Because of the suggestion by Erös (1933) and Jacobson (1939) that the argentaffin cells of the gastro-intestinal tract are concerned in the pathogenesis of the liver-deficiency macrocytic anaemias in man, we paid special attention to these cells in our experimental material and found them normal in appearance, number, and distribution in the stomach and intestine (Cameron, Watson, and Witts, 1950). The nervous plexuses of the gut are normal and there are no abnormalities in sections of the spinal cord. We saw no clinical symptoms of nervous disease even in animals which had been kept alive with folic acid.

The culs-de-sac are usually filled with a thick, dark, liquid material. This consists mainly of the bodies of bacteria with little food residue or desquamated mucosa. The bacteriological findings are much as if the ordinary flora of the caecum had ascended to the loop and the ileum. In the ileum itself there is a great increase in coliform organisms, a decrease in lactobacilli, and a corresponding increase in alpha-haemolytic streptococci.

Post-operative Developments

After operation those rats which do not die from surgical complications in the first few weeks may remain apparently well for long periods. Anaemia develops, often quite suddenly, after an interval which averaged about 90 days in a large series of rats, the range being from 26 days to 6 months. Failure to develop anaemia is sometimes explained by the formation of fistulae or blocking of the loop by adhesions, and similar happenings may account for some of the occasional spontaneous remissions. Nevertheless some animals in which the anatomical stage is set for anaemia do not become anaemic. Quite apart from anaemia, the expectation of life is much diminished in operated rats,

and they not infrequently die for reasons which we do not understand. However, it will be seen from the Table that not many of the rats which survive the initial hazards of the operation will live for six months without developing anaemia. Anaemic animals are perceptibly pale and listless, and may lose weight, but do not show other evidence of disease unless they develop pyogenic infection, to which they are more susceptible than healthy animals. Death may follow within a week of the onset of anaemia, and life is rarely prolonged more than three weeks without treatment, though an occasional anaemic rat has lingered for months and others have had remissions and relapsed again.

The Blood

All blood counts have been done on tail blood, and we have collected a large number of normal data (Cameron and Watson, 1949). The normal haemoglobin of female rats, which we used in all except the earliest experiments, was 13.8 g. per 100 ml. We define anaemia as a haemoglobin value below 10 g., although many of our rats had fallen much below that level before coming under treatment. In a small control series of anaemic rats allowed to die without treatment the haemoglobin at death averaged 5.8 g. per 100 ml., with a range of 2.7 to 8.5 g. per 100 ml. Macrocytosis is always present. In determining the size of the red cells we have relied more heavily on the red-cell diameter, which is a direct measurement, than on the mean corpuscular volume, which includes two sources of error—the red count, and the haematocrit.

From a large series of Price-Jones curves we have established the normal distribution of the red-cell diameter in the rat for our particular technique. The limits of normal for the mean cell diameter in the female rat are 5.73 and 6.56 μ , with an average of 6.14 μ . The normal mean corpuscular volume is 49 μ^3 . In anaemic animals the presence of macrocytosis is shown by increase in the mean cell diameter and volume, and by extension of the Price-Jones curve beyond the upper limits of normal. The figures in one small series of 10 anaemic animals averaged 6.62 μ for the mean cell diameter, with a range of 6.37 to 7.33 μ ; and 55 μ^3 for the cell volume, with a range of 50 to 67 μ^3 . The mean corpuscular haemoglobin is often but not invariably increased.

Macrocytosis is usually obvious in the stained film. Poikilocytosis is never more than slight. The anaemic animals have an irregular reticulocytosis, which may increase from the normal 4% to about 20% as the anaemia worsens, and which is manifested in the stained films by polychromasia. Nucleated red cells are seen in the peripheral blood in all but the lightest anaemias. Leucocytes are not reduced in numbers and they do not show any measurable qualitative change. Marrow smears taken in life show that the cellularity of the marrow is normal or increased (Watson, Cameron, and Witts, 1948). The most striking change is a shift to the left in the maturation of the red-cell precursors. In some cases the increase in proerythroblasts and large basophil erythroblasts is noteworthy, but no cells are seen which correspond exactly with the megaloblasts of human pernicious anaemia.

The serum is crystal-clear and therefore no estimation of serum bilirubin has been attempted. The amount of urobilinogen excreted in the faeces is significantly increased (Badenoch and Watson, 1951). As the normal

daily excretion of urobilinogen roughly parallels the amount of haemoglobin in circulation, we have expressed our results in the form of the haemolytic index (Miller, Singer, and Dameshek, 1942). This is the figure obtained by dividing the daily excretion of pigment in milligrams by the total haemoglobin in grammes and expressing this fraction as a percentage. The haemolytic index in the anaemic rats is seven times as high as in the normals. Fat absorption was deficient in most of the operated rats, but many had steatorrhoea without anaemia and a small proportion developed anaemia without showing impaired absorption of fat. In this latter group there did not appear to be any sepsis or haemorrhage to explain the anaemia. Although, therefore, there is some correlation between anaemia and steatorrhoea, it is not absolute. It is probable that both steatorrhoea and anaemia are due to a common cause, and not that steatorrhoea causes the anaemia (Aitken, Badenoch, and Spray, 1950).

Latent *Bartonella* infection may be activated when rats with intact spleens are fed on deficient diets (Wills and Mehta, 1930), and it was therefore possible that our animals might have developed bartonellosis and anaemia as a result of nutritional deficiency produced by the intestinal lesion. Blood films from anaemic rats never showed the frank infection with *Bartonella* which is seen after splenectomy in susceptible animals. However, it is impossible to be sure of identifying small numbers of *Bartonellae* in stained blood films, and further work was necessary to be certain that the anaemia was not caused by bartonellosis. Two measures were taken. The first was to maintain, with rigorous precautions against infection, a stock of *Bartonella*-free rats. These animals were prepared by operation in the usual way and it was found that anaemia developed as in the earlier experiments. The second measure was to treat a series of anaemic rats with neoarsphenamine, to which *Bartonella muris* is sensitive, and it was shown that the anaemia was not relieved by this therapy (Watson and Witts, 1951a). It is reasonably certain, therefore, that the development of anaemia in these rats is not dependent on *Bartonella* infection.

Responses to Treatment

A purified liver extract ("anahaemin") was given by intramuscular injection in single doses of 0.1 to 0.4 ml. to 17 rats with macrocytic anaemia after the earlier and milder operation, the self-emptying loop. In 10 rats there was some response to liver, and of the remaining seven which died six had some complication such as infection or perforation. Some of these rats responded on three successive occasions to an injection of liver extract. Response is shown by a reticulocyte crisis, which must be assessed with caution owing to the irregular reticulocytosis produced by the anaemia, and, more significant, by a rise in the number of red cells and in the haemoglobin. Macrocytosis diminishes, though the red cells may not return completely to normal size. These results appeared to us convincing, but we have not been able to get consistent responses to liver treatment in rats prepared by our present more rigorous procedure.

In the next experiment the blood counts of rats which had been submitted to the standard operation—that is, the 3-in. (7.5-cm.) self-filling loop—were checked at weekly intervals, and anaemic animals were assigned in sequence to one of four groups. One of these was a control group, and the others were treated respectively with anahaemin, pteroylglutamic acid, and vitamin B₁₂.

High doses were used, as from early experience it had seemed that these were necessary. We had already found that supplementing the basic diet with 200 μ g. of pteroylglutamic acid daily would not prevent anaemia developing, although this amount is well in excess of what is now thought to be the basal requirement (Darke and White, 1950). The material was given by injection three times a week in the following amounts: anahaemin, 0.5 ml.; pteroylglutamic acid, 7.5 mg.; and vitamin B₁₂, 20 μ g. This experiment provided clear evidence in favour of pteroylglutamic acid, which prolonged the duration of survival to approximately 80 days as compared with 20 days in the controls. The effects of anahaemin and vitamin B₁₂ were not significant statistically (Cameron, Callender, Watson, and Wits, 1949).

In a final therapeutic experiment a series of anaemic rats were treated with "aureomycin" incorporated into the basic diet. This was found to be as effective as folic acid in curing the anaemia and prolonging life in these rats (Watson and Wits, 1951b).

Discussion

A macrocytic anaemia which is usually fatal develops in a proportion of rats which have survived the operation for the formation of a blind loop in the small intestine. Most of these rats have also a mild steatorrhoea, but the correlation between anaemia and steatorrhoea is not absolute and the anaemia does not seem to be sequential to steatorrhoea. Anaemia is not an inevitable result of the operation, and cases of anaemia tend to occur in runs or crops, as if some common initiating factor appeared from time to time. This initiating factor may well be bacterial in nature—indeed, some of our evidence points to this—but it does not appear to be *Bartonella muris*, as the condition has been induced in a *Bartonella*-free stock and does not respond to neorarsphenamine. Owing chiefly to the high operative and post-operative mortality, the final yield of rats with anaemia is of the order of 20%, and in some series has been as low as 10%. It sometimes happens, therefore, that a fairly large consecutive series of rats are operated upon without anaemia developing. Nevertheless, this technique has been found to produce anaemia by other groups of workers (Broom, Emmet, and Woods, 1949, personal communication; Jarman and Underhill, 1951), and a similar condition has been produced by excision of the caecum in the rat (Plum, 1950).

The anaemia is of a macrocytic haemolytic character with reticulocytosis and increased pigment excretion. The bone marrow shows a shift of erythropoiesis to the left, but cells comparable to the megaloblasts or pernicious anaemia in man or the primitive erythroblasts of the foetal rat are rarely seen. The anaemia usually responds well to folic acid but not to refined liver extract or to vitamin B₁₂. It also responds to treatment with aureomycin by mouth, and there is a suggestion in the work of Jarman and Underhill (1951) of a response to sulphaguanidine. The anaemia differs from the blood disorder produced in the rat by folic-acid deficiency, which is macrocytic without haemolytic features and in which leucopenia is more prominent than anaemia (Kodicek and Carpenter, 1950). Nor is it identical with the condition produced in the rat by folic-acid antagonists, where the bone marrow has usually been hypoplastic (Oleson, Hutchings, and Subbarow, 1948; Philips and Thiersch, 1949), though megaloblastic arrest has been reported once (Franklin *et al.*, 1947), as has also an active non-megaloblastic marrow (Weir, Heinle,

and Welch, 1948). Thiersch and Philips (1949) point out that there are wide variations in the response of different species to folic-acid antagonists.

It is not easy to postulate the mechanism by which an intestinal cul-de-sac gives rise to anaemia in the rat, but there is sufficient evidence to permit limited speculation. We know that in these rats there is a bacterial invasion of the small bowel similar to that which occurs in people with gastro-colic fistula, and it is likely that the anaemia and steatorrhoea are similar in nature in the two conditions. The response to aureomycin, which may be presumed to check this invasion, is of particular interest in view of recent reports of the therapeutic value of aureomycin and penicillin in pernicious anaemia in man (Lichtman, Ginsberg, and Watson, 1950; Foy, Kondi, and Hargreaves, 1951) and the much older reports on the value of ileostomy in human pernicious anaemia (Seyderhelm, 1924; Dixon, Burns, and Giffin, 1925). These observations in rats and in man suggest that the intestinal bacteria have something to do with the absorption or the requirements of vitamin B₁₂ and folic acid. Support for this view comes from the work of Davis and Chow (1951), who found that aureomycin increased the vitamin-B₁₂ content of the faeces of rats given radioactive cobalt with their diet, measured by both radioactive and microbiological methods.

We have thought that when there is stenosis of the small intestine or a stagnant loop the decisive event in the production of anaemia may be a change in the flora of the loop or the small intestine. There are several ways in which this could lead to anaemia. It might cause the loss of an organism which synthesizes haemopoietic material, or the predominance of an organism which uses up haemopoietic material. It is possible that a toxin is formed, which acts other than by interference with the production or absorption of haemopoietic materials. The rapid onset of vitamin-B deficiency in patients who have undergone total gastrectomy suggests that such ideas are not extravagant (Brain and Stammers, 1951), and the production of pernicious anaemia by the fish tapeworm in the small intestine is another parallel (von Bonsdorff, 1948).

It would clearly be desirable to test such ideas by experiment both in man and in animals. Unfortunately the difficulties of detailed microbiological studies in the intestine are considerable, and, owing to the high mortality and frequent post-operative complications, the rat with an intestinal cul-de-sac has not proved an entirely satisfactory pharmacological preparation. We have been unable to diminish the mortality and complications greatly by improvements in technique. They seem to be closely related to the small size of the rat, and it may be necessary to use a larger experimental animal if the anaemia of intestinal stenosis and anastomosis is to be studied further by animal experiment.

Summary

The well-known clinical association of megaloblastic anaemia with intestinal stricture and anastomosis suggested that an operation of this type might be used to produce macrocytic anaemia in an experimental animal.

The formation of a small intestinal cul-de-sac in the rat leads to macrocytic anaemia in a proportion of cases, provided that the cul-de-sac has stagnant contents and is placed in the upper part of the small intestine.

The anaemia is associated with haemolysis, and sometimes with steatorrhoea. It responds well to folic acid or aureomycin but poorly or not at all to vitamin B₁₂.

From the available evidence the most likely cause of the anaemia is an alteration of the intestinal flora analogous to that which occurs in cases of gastro-colic fistula in man, and it is possible that the intestinal bacteria are in some way concerned with the absorption or utilization of haemopoietic substances.

We wish to thank our collaborators, whose names are mentioned in the references, and we are indebted to the Medical Research Council for a grant for technical assistance and expenses.

Nearly 800 new members were recruited in England and Wales to the National Hospital Service Reserve in November, bringing the total strength to 18,573. Of these, 1,706 are trained nurses and 16,839 nursing auxiliaries. Newcastle Hospital Region headed the November recruiting with 200 members, more than a quarter of the month's total of 796. Manchester came second with 102, and Bristol third with 94. Wales still has the largest total membership, 3,634, followed by the South-west Metropolitan Area with 2,277, and Newcastle with 1,643. A new recruiting drive was launched at the end of November by Miss Hornsby-Smith, Parliamentary Secretary to the Ministry of Health, with the aim of trebling membership and so bringing the Reserve well on the way to its peacetime objective of 80,000 members.

THE EFFECT ON BLEEDING-TIME OF AN EXTRACT OF BLOOD OF PATIENTS WITH RHEUMATOID ARTHRITIS

BY

Royal Northern Hospital

AND

JULIA GAMMON, B.Sc.

Formerly Deputy Biochemist to the Phillip Hill Clinic
at the Royal Northern Hospital

It has for many years been a matter of discussion among those interested in the origins of rheumatoid arthritis, that the disease may arise in apparent association with a large number of disturbing incidents, including infection, trauma, burns, excessive fatigue, the use of certain drugs, the metabolic crises of puberty, child-bearing, and the climacteric, and the psychological stresses and strains of normal life. That these incidents were the only cause was never believed, and statisticians who disproved to the hilt their sole significance might have excused themselves the labour of belabouring a donkey which had never lived.

Nevertheless, to experienced clinicians it was obvious that, though the majority of people could suffer with impunity the "slings and arrows of outrageous fortune," there were others who could not. Their interest was centred not on the hammer's stroke but on the anvil's ring, and was intensified by the description by Hans Selye (1936b, 1937) of the alarm reaction, which concentrated their attention upon the adrenal cortex. From the beginning it seemed likely, on clinical grounds, that the adrenals, if involved at all in the story of rheumatoid arthritis, would be found to be normal in this condition, for no evidence of adrenal deficiency had been observed in extensive investigations of the biochemistry of rheumatism. It seemed more likely that the error would be found in a mechanism in which the adrenal cortex served as an essential part, and that it would be in the control of the adrenals or in the response to the adrenals that the error would be found.

The Literature

Various Soviet authors (Synovich, 1940; Pshenichnikov, 1940; Novikov, 1941—reviewed by Clarke, 1941) claimed to have shown that the systemic use of local anaesthetics had resulted in a significant decrease in traumatic shock. Their results were confirmed by Ungar (1943), who found that "nupercaine" (cinchocaine) was especially effective. Extending his observations, Ungar (1944) found that several procedures were capable of protecting guinea-pigs and rats against subsequent trauma by causing an inhibition of histamine release. These procedures included the production of previous minor trauma and the administration of ascorbic acid, nupercaine, procaine, cocaine, adrenaline in unphysiological doses, a whole cortical extract prepared by Kendall, anterior pituitary extract, and, pre-eminently, adrenocorticotrophic hormone (A.C.T.H.). The protection afforded by these procedures (except the

administration of ascorbic acid) could be passively transferred in the serum from one animal to another, and was therefore due to a substance contained in the serum.

Inhibition of histamine release and consequent protection could be obtained, however, in adrenalectomized rats only by ascorbic acid and by adrenal extracts. Moreover, the inhibitory substance could not be demonstrated in the blood of hypophysectomized animals. Ungar concluded that certain procedures, including trauma, and the injection of peptone and certain drugs, causes the pituitary to release into the circulation a substance which stimulates the adrenals, which in their turn initiate the production of a protective substance. His results afforded a possible explanation of the observation of many workers that hypophysectomized and adrenalectomized animals are highly sensitive to trauma, and of the fact that the former may be protected by the administration of A.C.T.H. (Reiss, Macleod, and Golla, 1943). Ungar considered that the mechanism he postulated was a part of the alarm reaction described by Selye.

Action of Splenic Extracts

In 1945 Ungar published a further communication in which he claimed to show that the protective substance in question is derived from the spleen, from which it is released under the stimulation of the adrenal cortex. He had previously shown that substances which inhibited histamine release reduced bleeding-time and increased capillary resistance. He selected reduction of bleeding-time as the easiest and most reliable test for the substances involved in the endocrine reaction to trauma, and found that a reduction occurred after trauma in normal rats but not in hypophysectomized rats unless these were treated with A.C.T.H., adrenal extract, or splenic extract. Secondly, the reduction occurred in

adrenalectomized rats only if they were treated with adrenal extract or splenic extract. Thirdly, the reduction occurred in splenectomized rats only if they were treated with splenic extract. Similar effects could not be induced with other tissue extracts.

A curious point about the action of some splenic extracts now came to light. Small doses reduced the bleeding-time, but large doses increased it. This anomaly was subsequently found to be due to the presence in the extracts of two substances named by Ungar "splenin A" and "splenin B" (Ungar, 1945, 1946-7), whose pharmacological effects are opposed to one another. "Splenin A" is probably a derivative of ascorbic acid (Ungar, 1946-7), and "splenin B" is an ester of two or three fatty acids with a complex alcohol (Ungar and Damgaard, 1951). Ungar succeeded in demonstrating "splenin B" in human serum in various pathological conditions (purpura, haemolytic jaundice, paroxysmal haemoglobinuria, scurvy, and, at our instigation, rheumatoid arthritis) and from the serum of guinea-pigs after thyroidectomy. We have found it (or a similar substance) in the serum in cases of thyrotoxicosis and rheumatoid arthritis (Greene, 1950), but never in that of healthy persons.

The spleen has been for many years an organ of special interest to students of the rheumatic diseases because of its enlargement in Still's disease and Felty's syndrome. The possible role of the adrenal cortex had attracted a curiously limited attention since the publications of Selye (1936a) had begun. The work of Ungar suggested a possible line of attack, and in 1946 he was kind enough to test a number of unlabelled samples of serum sent to him from the Metropolitan Hospital. Two samples from cases of rheumatoid arthritis contained no "splenin A" but appreciable quantities of "splenin B." Four samples from healthy blood donors contained "splenin A" but no "splenin B." The serum from the

rheumatic patients was tested again after clinically successful treatment with A.C.T.H. and found to contain "splenin A" but no "splenin B" (Greene, 1950).

These results were encouraging, but it was clear that they might be fortuitous. The hypothesis advanced by Ungar rested on a foundation which seemed insufficiently solid—the estimation of bleeding-time in a comparatively small number of guinea-pigs. It was therefore decided to submit his method to a careful experimental trial.

Experiment 1

The first experiments were carried out to find the variation of the normal bleeding-time of guinea-pigs under carefully controlled conditions and the effect on it of a single dose of procaine. The bleeding-time was measured on the ear. Four readings were made, two on each ear, and the average of these was taken as the mean bleeding-time. The ear was pricked with a needle (1 mm. in diameter) and the bleeding observed and the wound blotted at intervals of five seconds. Bleeding was considered to have stopped when no issue of blood or serum could be detected for 10 seconds (Ungar, 1945). Six albino guinea-pigs of the same sex and approximately equal weight were chosen for the experiment. Each week the average bleeding time was measured on three of the animals before and 20 minutes after an injection of 0.4 ml. of 10% procaine, and, as a control, on three before and 20 minutes after an injection of 0.4 ml. of normal saline. This was continued for six weeks, so that both sets of guinea-pigs had alternate injections of procaine and saline. All injections were given subcutaneously. The results are recorded in Table I.

FIG. 1.—Histogram of normal guinea-pigs.

FIG. 2.—Histogram of guinea-pigs after saline injection (—) and after procaine injection (---).

The figures in Table I are expressed as histograms (Figs. 1 and 2). The first shows the variation in bleeding-time of normal guinea-pigs. Out of 144 measurements 77% lie between 100 and 155, with an average of 129 seconds. The form of the distribution is symmetrical and approximately normal. Fig. 2 shows that the measurements after saline injection are fairly similar. Out of 72 observations 76% lie between 100 and 155, with an average of 132 seconds. In contrast, the measurements after procaine injection are very different. Of the observations 79% lie between 75 and 135, with an average of 98 seconds. The histograms in Fig. 2 overlap to the extent of 33%. It is accordingly desirable to have a more sensitive test for a real difference than one based only on the appearance of the histograms.

The data from Table I give the variance analysis shown in Table II, demonstrating that each of the six guinea-pigs has a characteristic bleeding-time (variance

TABLE II.—Analysis of Variance (Experiment 1)

Source of Variance	Sum of Squares	Degrees of Freedom	Mean Square	Variance Ratio	Probability

* N.S. signifies non-significant in the sense that the differences found are no greater than would be expected to occur by chance. Significance is conventionally regarded as beginning at the once-in-twenty-times level.

† The residue was extensively examined in order to observe other systematic effects. None were found, and it was therefore expressed as a single item.

ratio=2.87, $n_1=5$, $n_2=264$, $0.05 > P > 0.01$), which persists from day to day (variance ratio=1.39, $n_1=10$, $n_2=264$, not significant). On all six days of the experiment the bleeding-times appear not to have changed (variance ratio=0.67, $n_1=5$, $n_2=264$, not significant). The normal bleeding-times of guinea-pigs do not differ from the bleeding-times after saline injection (variance ratio=1.62, $n_1=2$, $n_2=264$, not significant). The procaine-treated group differ considerably (variance ratio=120.59, $n_1=1$, $n_2=264$, $P=0.001$)—more, in fact, than would be supposed from the histograms, since here the bias of each individual guinea-pig has been eliminated. Clearly, procaine has been effective in reducing the bleeding-time.

Experiment 2

The second set of experiments was designed to compare the effects of serum from normal subjects and from patients suffering from active rheumatoid arthritis, all of whom had an E.S.R. of over 20 mm. in the first hour, measured by Wintrobe's method. In each case the serum was collected, pooled, and freeze-dried in 20-ml. portions and kept until required.

The serum was extracted with chloroform and acetone in order to separate Ungar's chloroform-soluble "splenin A" from the acetone-soluble "splenin

B." For each test 20 ml. of serum was shaken with three 20-ml. portions of chloroform. The combined chloroform extracts were filtered and evaporated to dryness, leaving a residue of "splenin A" and "B." To separate the "splenin B" from the residue, 20 ml. of acetone was added. The acetone was then decanted and evaporated, leaving the dry extract of "splenin

B." Just before testing, 2 ml. of saline was added to both residues, and 1 ml. per kg. used for injection.

In each case the average bleeding-times of the guinea-pigs were recorded every week, and the day before and one hour after injection. The experiment was continued for twelve weeks, the same guinea-pigs being used as in the previous experiment.

During the first six weeks each group of three pigs received alternately the saline extracts of "splenin A" and of "splenin B" from pooled normal serum. During the last six weeks they received extracts of "splenin A" and of "splenin B" from pooled rheumatoid serum. The results are recorded in Table III and Table IV.

TABLE V.—Analysis of Variance (Experiment 2)

Variation among the four groups of guinea-pigs before treatment ..	3,267	3	1,089	1.18	N.S.
Decrease in bleeding-time due to:					
Normal serum extract A ..	13,806	1	13,806	14.96	0.001 > P
Normal serum extract B ..	1,008	1	1,008	1.09	N.S.
Rheumatoid serum extract A ..	160	1	160	0.17	N.S.
Increase in bleeding-time due to rheumatoid serum extract B ..	17,600	1	17,600	19.07	0.001 > P
Residue remaining after removal of the above effects regarded as error arising randomly ..	111,731	121	923	—	
Total variation from all sources ..	558,492	575			

The data in Tables III and IV gave the variance analysis shown in Table V. From this it can be seen that the six guinea-pigs were more uniform than those used in the first experiment (variance ratio=0.85, $n_1=5$, $n_2=121$, not significant). The twelve occasions on which the experiment was carried out did not give rise to differences in bleeding-times (variance ratio=0.85, $n_1=10$, $n_2=121$, not significant). The four groups of observations before treatment did not vary more than would be expected ($F=1.18$, $n_1=3$, $n_2=121$, not significant). After treatment with serum extracts the groups differed. Table VI shows the differences.

TABLE VI

Treatment	Initial Bleeding-time	Alteration in Bleeding-time	Responding Bleeding-time
Normal serum extract A	122 seconds	Decreased 20	102 seconds
Normal serum extract B	128 "	" 5	123 "
Rheumatoid serum extract A	122 "	" 2	120 "
Rheumatoid serum extract B	129 "	Increased 22	151 "

and from the variance analysis (Table V) it appears that normal serum extract A decreases the bleeding-time (variance ratio=14.96, $n_1=1$, $n_2=121$, $P=0.001$) and rheumatoid serum extract B increases it (variance ratio=19.07, $n_1=1$, $n_2=121$, $P=0.001$). The remaining two treatments were ineffective at the dose given (variance ratio=1.09 and 0.17, respectively, $n_1=1$, $n_2=121$, not significant).

Conclusions

It is concluded that a factor or group of factors present in the "splenin A" extract of normal serum reduces bleeding-time, but is absent from a similar

extract from rheumatoid patients. A factor or group of factors is present in the "splenin B" extract of rheumatoid serum that increases bleeding-time, but is absent from normal serum. Both effects have been found consistently.

The experiments, while confirming the existence of the substances called by Ungar "splenin A" and "splenin B," give no indication of the manner or place of production of these substances. His view that they are produced in the spleen and that their production forms part of the general adaptation syndrome is at present under investigation.

We wish to express our thanks to Dr. G. Ungar for initiating us into his methods of extracting the "splenins"; to Mr. A. L. Bacharach and Mr. B. Basil, both of Glaxo Laboratories Ltd for their help in planning this experiment and undertaking the statistical analysis, respectively; and to Dr. W. J. Martin, of the Statistical Research Unit, London School of Hygiene and Tropical Medicine, for his helpful criticism.

THE STERILIZATION OF WOOLLEN FABRICS

BY

H. F. BARNARD, M.B., B.S.

Pathologist, Westwood Hospital, Beverley, E. York.

Air-borne infection is frequent in the case both of wounds and of infections of the respiratory tract. The infectious organisms are carried on dust or on droplets and droplet nuclei arising from the mouth and nose. Of the two, dust is probably responsible for greater degrees of air contamination (Hare and MacKenzie, 1946; Duguid and Wallace, 1948). Such infected dust arises for the most part from the movement of fabrics—for example, blankets, clothes (van den Ende, Lush, and Edward, 1940; Green, Challinor, and Duguid, 1945; Duguid and Wallace, 1948), bandages (Bourdillon and Colebrook, 1946), and handkerchiefs (Dumbell, Lovelock, and Lowbury, 1948), and to a somewhat less extent from floor-sweeping (Green, Challinor, and Duguid, 1945), although much of this floor dust has come in the first place from fabrics.

Dust-borne bacteria are relatively resistant to the bactericidal action of ultra-violet light and chemical aerosols (Twort, Baker, Finn, and Powell, 1940; Dumbell, Lovelock, and Lowbury, 1948). Correct ventilation can clear the air fairly rapidly (Bourdillon and Colebrook, 1946). To a large extent, however, control has depended upon preventing the release of dust, by oiling in the case of blankets (Thomas and van den Ende, 1941) and floors (van den Ende, Lush, and Edward, 1940), by adequate gowning in the case of clothes (Duguid and Wallace, 1948), and also, of course, by washing.

P25 534

Relatively little attention has been paid until recently to the adequate bacterial cleansing of the fabrics whence comes so much of the pathogen-bearing dust, though the problem has been appreciated by workers in this field. Bourdillon and Colebrook (1946) state that, "whilst a freshly laundered gown or clean sheet is almost sterile, all woollen or flannel articles must be regarded as infected." Colebrook, Gibson, Todd, Clark, Brown, and Anderson (1944) reported finding haemolytic streptococci in freshly laundered blankets in a hospital and, at the same time, in burns, both organisms being of the same type. A similar experience led here to a convenient way of sterilizing blankets.

Cross-infection and Woollens

For some years efforts have been made to reduce the minor infection of clean wounds and similar cross-infections. Mostly these have been caused by the *Staphylococcus aureus*, the majority of strains in hospital cases being penicillin-resistant. Periodical checking of the staff has always shown that some 50% are nasal carriers of this organism, many of these, too, being resistant strains. However, phage-typing of the organisms recovered from patients and staff, kindly carried out by Dr. V. D. Allison, cast doubt on the direct nurse-to-patient route of spread, as the type in the wound often did not correspond with that found in the nurses in contact. Therefore, when the majority of freshly laundered blankets were found to contain *Staph. aureus*, it became desirable to find a convenient way of sterilizing these and closing this possible route of spread.

Woollens, as we know, shrink in hot water, so that though other fabrics are washed at a temperature lethal to most organisms, woollens are not so treated. As Bourdillon and Colebrook (1946) state: "Whilst clean linen and cotton goods are almost sterile, flannel and woollen goods are in a very different category, since in most laundries they are not heated to a bactericidal temperature." In the present case blankets are churned for 10 minutes at 43° C., and staphylococci in test squares of blanket survive the procedure readily. If a piece of blanket is heat-sterilized and then washed in the machine with the routine ward blankets and thereafter cultured, it is found to have picked up, in what appears to be full measure, the bacterial flora from the other blankets. Evidently transfer of organisms between blankets in the wash readily occurs. It is significant, therefore, that one has found occasionally used blankets to be grossly infected with staphylococci.

Sterilization of Blankets

The poor bactericidal results of laundering methods for woollens have led in recent times to attempts being made to find better ways. Bactericidal temperatures being detrimental to wool, attention has been turned to chemical disinfection.

Van den Ende and Spooner (1941) impregnated squares of fabric by soaking in various bactericidal solutions and, when dry, sprayed them with a culture of haemolytic streptococci or with an infected powder. Later the fabric was shaken over an agar plate or wiped on it. A number of bactericides were tried, but none was considered of practical value. Puck, Robertson, Wise, Loosli, and Lemon (1946) used a similar method, and though the fabric, when dried, retained much of the bactericide, the haemolytic streptococci sprayed on to it could later be recovered by culture. Contact between

the two was evidently insufficient, probably owing to the bactericide failing to spread readily over the fibres of the fabric. Rountree (1946) and Rountree and Armytage (1946) found that blankets destroyed bacteria when oiled by the method recommended by Harwood, Powney, and Edwards (1944). The bactericidal agent was the detergent cetyl pyridinium bromide (C.P.B.), which remained with the oil in the blanket. Haemolytic streptococci sprayed on to the treated fabric could not be recovered later by wiping it on agar or by washing it in broth. The fabric was not harmed in any way by the process, nor were a small group of people found to be sensitive to contact with the impregnated fabric.

Dumbell and Lovelock (1949) have studied disinfectants suitable for impregnating handkerchiefs to render them self-disinfecting. *Staph. aureus* in saliva was soaked into the treated cotton fabric, which, when dry, was shaken over agar plates. The most active agent tried, hexyl resorcinol, was of prohibitive cost, but octyl cresol and "alkyl" resorcinol were considered practicable. They considered that for handkerchiefs C.P.B. was unsuitable, as it had been reported by Williams, Clayton-Cooper, Duncan, and Miles (1943) that some people (under 1%) are sensitive to its local application.

Vaughan, Sotier, Hill, Simpson, and Lee (1948) examined ways to sterilize woollens in a laundry wash process. In this work there was no attempt at impregnation to render the fabric self-disinfecting. Chlorination was considered the most practical method, and the agent causing the least harm to dyes and fabric was sodium benzene sulphone chloramide ("monochloramine B"). This method was found suitable for the large-scale treatment of clothing in the American Army. Small fabric squares infected with *Bact. coli* and *B. subtilis* were included with the clothing treated, and were afterwards found to be sterile.

Before we became acquainted with the above relevant literature, consideration had been given to chemical disinfection of blankets. For reasons of cost, toxicity, damage to fabric, and so on, all but a few disinfectants appeared to be unsuitable. Trial use was made of calcium hypochlorite in the form of eusol powder over a period of some months, pending the discovery of a better way. It was, in the strength used (2.5% of eusol powder), less adequately bactericidal in the laundry than in the test-tube and, moreover, it produced slight but noticeable hardening of the wool.

C.P.B. seemed to deserve further consideration. It is a cation-active detergent, and as "fixanol C" is manufactured by I.C.I. The high bactericidal activity of certain of the surface active agents has been extensively examined since the publication of Domagk (1935). Quisno and Foter (1946) examined cetyl pyridinium chloride and found it unusual in being highly bactericidal over a wide range of pH. Van den Ende, Edward, and Lush (1941) had tried C.P.B. and found that, though it left the fabric bactericidal, it gave a "harsh texture and unpleasant odour." Rountree found fixanol in solution highly bactericidal, especially to Gram-positive organisms. She found that blankets soaked with oil and fixanol solution and dried were virtually sterile for many weeks: 1 in 800 in the blanket (in addition to the oil) was adequate, but 1 in 1,600 was much less so. Patch tests with 1% solution gave no reactions in 17 people.

The purpose of the oiling is to reduce dust release, and, while Rountree (1947) found that it brought no

reduction in surgical cross-infection, Wright, Cruickshank, and Gunn (1944) were able to show a reduction in cross-infection in measles wards. The process, however, is not without disadvantages. It is not very easy for a normal laundry to control, it is somewhat expensive, and the finished product is a slightly oily blanket—though the work of the U.S. Navy Medical Research Unit (1946) would seem to have overcome much of the trouble and cost. It seemed, however, that a trial of fixanol C without oil would be worth making.

Present Investigation

The concentration necessary was suggested by the above oil and fixanol experiments—namely, one part by weight of undiluted fixanol to 800 parts by weight of blanket. It was found that, in the laundry after hydro-extracting, the water held in a blanket before air-drying averages one-third of its dry weight, a gain in weight of 33%. Thus, to attain a final 1 in 800 the blanket would have to be washed in a 1 in 200 solution of fixanol in water and dried without rinsing. The bactericidal effect of different concentrations was tested, the blankets being shaken over blood-agar plates. With this method of culture the number of particles released varies according to the state of the blanket, but it parallels roughly the dispersal of particles in bed-making. Ludlam's medium (Ludlam, 1949) and Chapman's salt agar (Chapman, 1945, 1949) were tried as selective media for staphylococci. The latter was found of some value in this

Blankets After Treatment with Various Concentrations of Fixanol

	Concentration of Fixanol in Dry Blanket				
	1 in 800	1 in 1,600	1 in 3,200	1 in 6,400	0
No. of colonies on agar	±	0	+	++	++++
Size of inhibition zones on staph. spread plate	++++	++	+++	+	0

FIG. 1.—Sterilization of blanket with fixanol C. Above: untreated. Below: treated.

work, but blood agar remained the principal medium. No growth was obtained with final dry concentrations up to 1 in 1,600, and at 1 in 6,400 growth was much reduced and no staphylococci were found (Table and Fig. 1).

The fixanol on the dried blanket coats the individual fibres and readily passes again into solution on contact with moisture. This can conveniently be demonstrated by shaking the treated blanket over a plate which has been freshly spread with *Staph. aureus* broth culture and dried. After incubation, as may be seen in Fig. 2, each fibre is surrounded by a narrow zone of inhibition where no growth has occurred.

FIG. 2.—Inhibition zones around wool fibres coated with fixanol C.

The concentration of fixanol forming in secretions that reach the blanket will depend upon the volume of secretion and the way it spreads amongst the fibres. A droplet of saliva on a treated blanket examined under a hand lens can be seen to spread to a limited extent (Fig. 3). It is reasonable to suppose that in such a droplet the strength of fixanol lies much above the minimum lethal concentration for staphylococci, which is 1 in 200,000, and even above that for the Gram-negative bacilli, 1 in 1,000. For routine use 1 in 6,400 dry content was chosen. As a check a 1 foot square (0.093 m.²) of blanket was heavily infected in a diluted broth culture of staphylococci, dried, and then washed with 16 other blankets in this chosen concentration. Shaken over blood agar before treatment, the square grew a shower of staphylococci, but afterwards none at all. Further, a blanket that had been treated was some weeks later infected with staphylococcus as above, dried, and shaken over agar. This also grew no staphylococci.

The same procedures were carried out with *Pseudomonas pyocyanea*, an organism which, with the exception of the tubercle bacillus, is probably the most resistant pathogen to this bactericide as to so many others. There was, as with the staphylococcus, complete failure to recover any of the test organisms when the blanket was infected before being treated with fixanol. When, however, a culture of *Ps. pyocyanea* was sprayed on to or soaked into a blanket square impregnated with fixanol in the usual strength, it was readily recovered later. The same applied even when the concentration of fixanol was raised four times. Evidently, in such absorbed fluids, the concentration of fixanol does not reach the lethal level for *Ps. pyocyanea*.

Thus, with this procedure the blanket leaves the laundry virtually sterile. Moreover, it will apparently retain, for a considerable period, sufficient material to destroy any staphylococci that may be picked up in secretions. The cost of the detergent is approximately 1d. a blanket, and the procedure is straight-

FIG. 3.—Saliva droplet adhering to wool fibres coated with fixanol.

forward. The impregnated blanket has a slightly smooth feel, it has no smell, and in routine hospital use for all blankets for a year there has been no indication of patients showing sensitivity to the treated blankets.

Discussion

The much higher frequency with which penicillin-resistant strains of staphylococci are recovered from hospital cases, as compared with those at home, is largely referable to cross-infection (Rountree and Thomson, 1949; Barber, Hayhoe, and Whitehead, 1949). Nasal carriers of such strains among hospital staff are also frequent, and there is a tendency for newly arrived nurses to acquire the prevailing phage type. Though staff may directly infect patients, both might, as postulated by the *Lancet* (1949), be infected by the hospital environment. The nose is an effective dust filter (StClair Thomson and Hewlett, 1896). This is by virtue of air turbulence and impaction of particles against the moist walls. Thus a ward nurse has something in common with a slit sampler.

It was of interest, therefore, to sterilize the hospital blankets for a period and to observe the effect on the incidence of carriers, and also of cross-infected wounds. Briefly, it may be reported that in three months there was no reduction in the carrier rate, while for wounds the small numbers left the matter in doubt, a certain amount of cross-infection still continuing. No doubt, as observed by Girdlestone, Bourdillon, and McFarlan (1951), there are a multiplicity of sources of infection. A wider trial is desirable in which the sterilization of clothes and other fabrics deserves consideration.

Whilst uncertainty remains on many points, it is not without importance that, as many have observed, pathogens are surviving for long periods in the woollen fabrics of our most immediate environment, and, moreover, that perhaps now this need no longer be so.

Summary

Cross-infection of wounds in a hospital has been investigated. Attention is directed to dust from blankets. From freshly laundered blankets *Staph. aureus* was frequently obtained, which organism readily survived the laundry process. During laundering bacteria pass from one blanket to the next.

Impregnation with cetyl pyridinium bromide (fixanol C) has been found a satisfactory way of sterilizing blankets. They remain, to a large extent, self-disinfecting.

I am indebted to Dr. W. H. James, medical superintendent of the Westwood Hospital, Beverley, for his valuable observation and advice on the clinical aspects; to Dr. W. Goldie, pathologist

to St. James's Hospital, Leeds, for his most helpful criticism of the manuscript; and to Mr. A. Manby, senior technician, Westwood Hospital, Beverley, for preparation of the photographs.

BACTERIOLOGY OF VAGINAL FLORA AFTER USE OF INTERNAL TAMPONS

BY

ELIZABETH N. BRAND, M.D., D.P.H.

The vaginal tampon is being used with increasing frequency for the absorption of the menstrual flow, but this subject has received little attention from the medical profession in this country, though there still may be a fair amount of prejudice against its use.

Correspondence for and against it appeared in the *British Medical Journal* (1938, 1939). For over 14 years Partridge (1939) had advised its use amongst her patients without there being any complaints or untoward results. Barton (1942) reported on the advantages of intravaginal tampons as menstrual guards.

The matter has been investigated fully by gynaecologists in the U.S.A. Sackren (1939) carried out an investigation on 21 patients and found no irritation in the vaginal or cervical tissues after the use of internal tampons. Thornton (1943) investigated 110 subjects for one to two years and arrived at the same conclusion. Karnaky (1941, 1943) claimed beneficial results in cases of sterility. Magid and Geiger (1942) investigated the bacterial flora in the vagina and cervix after the use of tampons in 25 women, over two menstrual periods,

existence of developmental language difficulties, and he gives a number of diagnostic features of what he believes to be a specific clinical entity. These include uneven and ill-formed handwriting, slow and stumbling reading (with many mispronunciations and occasional reversals), numerous and bizarre spelling errors, and a bad record in linguistic school subjects. Although suitably cautious about their cause, Gallacher inclines to Orton's well-known theory that such defects result from failure to establish normal hemisphere dominance. But although this hypothesis has proved attractive to many, it has so far failed to establish itself firmly in orthodox neurological theory.

A more extensive study of the dyslexic component (congenital word-blindness) in specific language defect has been reported by Hallgren.² Unlike earlier workers, he has been unable to find evidence of a direct association between "developmental dyslexia" and left-handedness, left eye dominance, or mixed eye-hand preferences. These negative findings militate to some extent against the view that anomalous cerebral dominance is a causal factor. On the other hand, Hallgren reports evidence pointing to the congenital origin of the disorder, in a majority of cases at least. Data derived from examination of the parents and siblings of 116 dyslexic children lead him to conclude that the defect follows a "monohybrid autosomal dominant mode of inheritance with practically complete manifestation." If this work be confirmed, it would suggest that specific dyslexia is an inherited defect comparable to colour blindness and that environmental factors play little, if any, part in its causation. The possibility that they may exacerbate a congenital condition is not, however, excluded. The implications of Hallgren's findings for the schooling of children with developmental language defects remain to be assessed. Although some response to remedial methods is often claimed, it appears distinctly doubtful whether this justifies the time and trouble spent on treatment when the defect is certainly congenital. In such cases less attention might be given to the disability itself and more to the development of knowledge and skills in unaffected fields of performance. Such a course, combined where necessary with appropriate psychiatric guidance, might go a long way towards reducing the affected child's sensitivity about his handicap and equipping him for a vocation in which technical skill counts for more than symbolic sophistication.

CHOICE OF ANTIBIOTIC FOR PNEUMONIA

The recent trial¹ published by the Medical Research Council subcommittee showed clearly that penicillin was at least as effective as aureomycin or chloramphenicol in the treatment of bacterial pneumonia—and very much cheaper. In the winter of 1949–50 a group at the Philadelphia General Hospital carried out a similar but smaller-scale trial on a total of 93 patients, and came to much the same conclusion.² Indeed, the drop in temperature was most sudden, and secondary

risers rarest, in those who received penicillin, even when given orally in a first dose of 500,000 units followed by 250,000 units every 12 hours to a total of 3,000,000 units. End-results were the same with each treatment. Penicillin has the advantage of fewer toxic reactions than the other antibiotics. Because it produces the most rapid response, the authors believe that it is best used even in cases where the pneumonia is not certainly bacterial but may be viral, since it is bacterial pneumonia which has the high mortality.

NUTRITION IN NEW GUINEA

Breadth of knowledge as well as vision is needed in the drawing up of reliable plans to raise the standard of living of the people in the colonial territories.¹ More than one scheme has already come to grief because it was launched without sufficient testing of its suitability. What the planners have apparently failed to realize is that success in a temperate zone gives no guarantee of an equivalent success elsewhere. The report² of the New Guinea Nutrition Survey Expedition suggests that the lesson has been well learnt by a group of Australian scientists. Undertaken at the request of the Administrator of Papua and New Guinea and the Department of External Territories, Australia, the expedition's main object was to collect enough information about native dietary patterns and food habits to make possible the drawing up of sound and acceptable ration scales for employed labourers. Secondary aims were the study of normal production and consumption and the collection of data which would help to show whether native agriculture could combine cash and food crops without detriment to the latter.

The field staff consisted of a medical officer, two biochemists, a parasitologist, a nutritionist, an agriculturist, a dental officer, an anthropologist, and a photographer, and they were assisted by various members of the staff of the Institute of Anatomy working in Canberra. The expedition visited five different villages, spending approximately one month in each, and the combined efforts of the different members of the team have provided an all-round review of the situation prevailing at the time of the visit in three of the villages. In the remaining two villages the work was less comprehensive. The people surveyed lived mainly on starchy roots, sago, or bananas, with no milk and practically no flesh food, yet no signs of malnutrition were detected. The weakness of the survey was the short time spent in each village. Experience in other territories has shown how necessary it is to live closely with the people under observation throughout at least one complete agricultural cycle; seasonal fluctuations tend to be much greater than expected, and an understanding of the cultural outlook of an unknown community is not achieved in a short time. The writers of the report seem to have realized this, and most sections end with a call for further investigations. The danger is that readers may be less aware of the many things that were not found

out and too prone to quote figures which may apply only to one month in the twelve. This is not to decry the value of the observations that were made but only to point out that they were extensive rather than intensive. Carefully interpreted, they can be of the greatest use, not only to the territories concerned but also to medical scientists, agriculturists, and others elsewhere.

COMPULSORY RETIREMENT

The age for retirement of doctors in the hospital service has been fixed at 65. Most consultants, knowing that able men have been trained to take their place, have no great objection to this provided they can, if they want to, continue their work in private practice or in other directions. It would in fact be a sad waste of knowledge and experience if all medical men ceased the practice of medicine at the age of 65, or even much higher, and it is disturbing to read recent letters from doctors who have had their contracts with hospitals terminated under the age rule and are left with little or no work to do. Consultants retiring now under this rule have not served in the N.H.S. long enough to qualify for a pension, and their opportunity to make a living out of private practice is much less than it was before 1948. Pathologists and radiologists are particularly hard hit, for many of them did all their work at voluntary hospitals and were paid by salary. The Consulting Pathologists Group Committee of the B.M.A. has recently been considering how to make things easier for those who have to retire under the present rule without a pension (see *Supplement*, page 4). There is in fact a good case for extending the contracts of pathologists beyond retiring age because of the difficulty of finding suitably experienced men to fill consultant posts in this specialty. The clinician is in a far more favourable position, for the granting of an honorary contract to him enables him to continue his work by attending patients in private beds, while an honorary contract is valueless to a pathologist who has no private laboratory of his own, unless he is also given the right to use a hospital laboratory. This might cause difficulties in some laboratories, but with good will and common sense it should be possible to ensure that retired pathologists, and other consultants in like position, can continue to exercise their skill and at the same time overcome the financial hardship caused by the enforced termination of their contracts.

WINTER EPIDEMICS

Lack of knowledge about the differences between the several forms of respiratory disease occurring in epidemics during the winter has delayed the development of specific methods of treatment. But the control of influenza by immunization now seems to be within the bounds of possibility, and the important task of the moment is to obtain information which will not only be of use to laboratory workers but will also help hospitals to meet the strain of a sudden winter epidemic. The person best placed to collect evidence about local outbreaks is the district medical officer of health.

His sources of information, according to a recent suggestion of the Ministry of Health,¹ should be general practitioners, industrial and Service medical officers, the regional controllers of the Ministry of National Insurance, and registrars of deaths. Besides letting the Ministry know as soon as he finds that respiratory disease is becoming unusually prevalent, the M.O.H. must warn the Public Health Laboratory Service at the earliest indication of an outbreak, so that arrangements can be made to collect material for investigation. For this purpose it is hoped that some general practitioners will act as "spotters," who will be in direct touch with the nearest laboratory, though of course the results of tests will probably not be ready in time to help the practitioner in his treatment of an individual patient. By these means the Ministry hopes "that representative strains of virus will be isolated from all the main centres of population at the time of the first appearance of influenza." Meanwhile the Medical Research Council is to study the production and arrange for the trial of a vaccine made from influenza virus cultured in fertile eggs. The hopes that this vaccine may eventually be used with success on a large scale have been recently strengthened by the discovery that its antigenic property is greatly enhanced by the addition of oily adjuvants.

SALMONELLA MINNESOTA INFECTION

The first large outbreak in Britain of food-poisoning caused by *Salmonella minnesota* has occurred in Northamptonshire and the surrounding country, and some information about it is given at page 53. Several hundred people are known to have been affected, and there are thought to have been more whose symptoms were so mild that they did not seek medical attention. There have been two deaths—a woman aged 77 and a man aged 78. The infection has appeared chiefly in the elderly, as is usual in outbreaks of this kind.

With commendable promptitude the public health medical officers discovered the source of the outbreak in meat pies manufactured at a Northants pie factory. How the pies became infected is still a mystery. They contained meat imported from Denmark, and it has been suggested that this may have been contaminated with the organism. But *Salmonella minnesota* is being reported in this country with increasing frequency, and it seems quite possible that the imported meat had nothing to do with the outbreak.

The Salmonella Reference Laboratory, Colindale, identified the first four human cases in Britain of infection with this organism in 1950. In 1951, 23 cases were identified apart from the present outbreak. Most of them were in Inverness and the Aberdeen area, but others were identified in diverse parts of Britain, including one case in London. Two cases in Aberdeen proved to be fatal. On December 10, 1951, the laboratory identified the organism in a specimen taken from a case in Northamptonshire. The possibility of a connexion between this case and the outbreak is no doubt being investigated.

¹ *Mon. Bull. Minist. Hlth, Lond.*, 1951, 10, 280.

² *J. Hyg., Camb.*, 1938, 32, 716.

This salmonella is so named because it was isolated from a three-weeks-old turkey poult in Minnesota in 1936, and Edwards and Bruner² first described its characteristics two years later. In Britain it has not yet been isolated from animals. Whether this outbreak is the herald of more to be caused by *Salmonella minnesota* remains to be seen, but the increasing frequency with which the organism has been identified over the last two years suggests that it may be a new addition to the various groups of organisms apt to cause outbreaks of food-poisoning.

STEROID METABOLISM IN IDIOPATHIC HIRSUTISM

In normal women the urinary excretion of 17-ketosteroids shows no definite variations in the course of the menstrual cycle.³⁻⁷ Pregnanediol, on the other hand, appears in the urine during the luteal phase.⁸⁻⁹ In women with idiopathic hirsutism Koets¹⁰ found a cyclic variation in excretion of 17-ketosteroids, the peak of excretion coinciding more or less with the probable time of ovulation. Merivale¹¹ has recently reported similar findings in hirsute women, but by correlating the excretion of 17-ketosteroids and pregnanediol he has shown the peak in the excretion of the former to coincide fairly closely with that of the latter, and to be absent in a hirsute woman who did not ovulate. These facts are of great interest, for casual (and even careful) clinical and laboratory investigations have hitherto yielded negative results and led many observers to conclude that the fundamental defect in idiopathic hirsutism was most likely an excessive response by the affected hair follicles to an apparently normal stimulus—whatever that might be—rather than an abnormal stimulus.

Engstrom and Munson,¹² studying the metabolism of testosterone in normal women, have found that it is converted into 17-ketosteroids to a greater extent during the follicular phase than during the luteal phase—the difference being statistically significant. If it is assumed that the endogenous precursors of the 17-ketosteroids are broken down in the same way, it follows that in normal women more of these precursors are secreted in the luteal phase than in the follicular phase of the cycle. Since their conversion to 17-ketosteroids is less in the luteal phase, the urinary output would remain more or less constant throughout the cycle. Perhaps, therefore, this cyclic fluctuation of 17-ketosteroid precursors is enhanced in women with idiopathic hirsutism, secretion during the luteal phase being even more marked than in normal women. These substances include among their number steroids with androgenic activity, and this train of reasoning leads after

all to the suggestion that relatively more androgens are secreted in hirsute than in other women. The situation, however, is not so simple as that. Merivale, for instance, impressed by the coincidence of the peaks of 17-ketosteroid and of pregnanediol excretion in hirsute women, considers that the connexion may not be merely fortuitous, that the substance (measured by the Zimmermann reaction) apparently increasing the 17-ketosteroid output may, in fact, be a 20-ketosteroid (such as a pregnanolone), and that it may thus indicate an abnormality of progesterone metabolism.¹³ Engstrom and Munson envisaged yet a further possibility. The conversion of 17-ketosteroid precursors into 17-ketosteroids is regarded as a function of the peripheral tissues—the end-organs, in fact, including perhaps the hair-follicles—and increased conversion may represent an increased response on the part of the end-organs. Such could be the case in hirsute women, their abnormality residing in the failure of the end-organs to decrease their response during the luteal phase. This possibility could be examined by repeating the experiments of Engstrom and Munson in hirsute women; the finding of no difference in the conversion of testosterone to 17-ketosteroids in the follicular and luteal phases would be supporting evidence, provided that the extent of conversion was similar to that found in normal women during the follicular phase.

That the above considerations are nowhere near the whole story is clear from such facts as the absence of any increased 17-ketosteroid excretion—or even decidedly low excretion—in some cases of hirsutism, such as those due to arrhenoblastoma or those associated with bilateral solid enlargement of the ovaries. The field is obviously still wide open for further research.

"FAMILY DOCTOR"

A subscription form for *Family Doctor* was inserted in the *Journal* of December 22, and it is hoped that many doctors will return the forms, filled in, to support this publication of the B.M.A. Designed to be a popular health journal for the lay public, *Family Doctor* made its first appearance in April, 1951, and got off to a flying start. The issues published monthly since then have covered a wide field and have commanded the interest of a steady corps of readers. Medical men and women should find *Family Doctor* a practical magazine which will, by helping their patients, thus help them in their daily practice. The essential function of *Family Doctor* is to promote healthy living both by positive precept and by emphasis on the preventive aspects of medicine. The dish is garnished with articles of popular and topical interest. The January number contains, among its features, "Profile of Niall MacGinnis," by Dr. Cormac Swan; "Surgeons," by Sir Heneage Ogilvie; "Fact and Fancy in Pregnancy," by Professor Dugald Baird; an editorial on hypnotism; and a new poem by Walter de la Mare. General practitioners, in particular, would do a useful service by persuading their patients to become subscribers to *Family Doctor*, which costs only 1s. a month.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE PAINFUL SHOULDER

BY

R. J. W. WITHERS, M.D., M.Ch., F.R.C.S.Ed.

Lecturer in Orthopaedics, Queen's University, Belfast; Orthopaedic Surgeon, Royal Victoria Hospital, Belfast

Pain in the shoulder may result from lesions of a gross nature, such as fractures, dislocations, tuberculosis, bone tumours, and infective arthritis, or may be due to abnormal conditions of the cervical spine, the apex of the lung, and the pleura, or to obstructive lesions of the cervico-axillary outlet. Pain may also be felt in the shoulder from visceral disturbance, notably from heart and gall-bladder disease.

When these lesions are excluded there remains a well-defined group of conditions of the shoulder in which there is pain, limitation or alteration of shoulder movement, sometimes muscular wasting, and usually no radiographic evidence of abnormality. It is to this group that the term "painful shoulder" is applied, and in considering the underlying pathology certain anatomical and physiological features of the shoulder must be recalled.

Normal Shoulder Movement

The movement of full elevation of the arm includes motion at no fewer than four joints: the sternoclavicular joint is involved mainly in the early phase of elevation, the acromio-clavicular mainly towards the end of this movement, whilst gleno-humeral and scapulo-thoracic movements are occurring throughout all phases. The participation of each of these four components in the entire movement of elevation of the arm is simultaneous and not successive, and each shoulder muscle is known to contract throughout the full range of elevation, though with a peak of maximal contraction at a selective and critical phase.

The muscles acting at the gleno-humeral joint can be divided into two groups—a superficial set, essentially the deltoid, and a deep set consisting of the spinati, the subscapularis, and the teres major and minor. These two groups are separated by the subdeltoid bursa, and each has a different though equally important part to play in shoulder movement. The deep muscles act by tensing, fixing, and depressing the humeral head against the glenoid cavity, so that the superficial muscles, the deltoid, can effect elevation of the humerus at a stable hinge. One set is useless without the other. If the hinge is unstable, as in ruptures of the tendons of the deep muscles, the deltoid cannot elevate the humerus or at best can only do so weakly or incompletely. If the hinge is fixed, "stuck" as it were, by inflammation or adhesions in the deep tendons, elevation is again impossible no matter how powerful the deltoid may be. The deep muscles therefore assume an extremely important position in gleno-humeral movement and their anatomy is worthy of further consideration.

Effect of Advancing Years

In the adult the capsule of the shoulder-joint is fused with the overlying deep muscles, but in the infant these structures are separated by areolar tissue, the tendons

being short and the muscle fibres extending to within a few millimetres of their humeral attachments. As age advances the tendons become longer, and the degree of adhesion between them and the capsule also increases, so that in old age the fusion may well be complete. These changes are most marked at the upper part of the capsule, so that in adult life the entire supraspinatus tendon and the upper parts of the tendons of the subscapularis and infraspinatus are intimately fused with one another and with the shoulder capsule. I have called this fused structure the physiological hinge.

Post-mortem investigations have shown that degenerative changes, ranging from superficial fibrillation to complete rupture, of this fused tendino-capsule occur in arithmetical progression as age advances, and that after 75 years fully 50% of all subjects coming to post-mortem examination have incomplete or complete ruptures of the upper part of the fused shoulder capsule. The physiological hinge of the shoulder-joint therefore tends to degenerate as one gets older, and it is suggested that most cases of "painful shoulder" are due to this degeneration, influenced by trauma or by irritative and inflammatory changes in the tendino-capsule itself. Support is given to this suggestion when it is realized that few cases of "painful shoulder" are seen before the age of 45—that is, before the age when degeneration starts. If it is accepted that the pathological changes usually start in the capsule in relationship to the supraspinatus tendon, it is easiest to consider the clinical states produced under an all-embracing term "the supraspinatus syndrome," thereby avoiding the confused and often misleading nomenclature which has been adopted in the past, though never forgetting that other parts of the shoulder capsule are affected by degenerative or inflammatory change in the worst cases.

Clinical Groups

Three groups can be recognized, all painful and each with a characteristic symptom.

1. The arm cannot be elevated by the patient nor can he sustain it in an elevated position when so placed by the examiner, but it drops uselessly to the side. This is the *useless arm or drop-arm* group, and the underlying pathology is a rupture of the supraspinatus tendon.
2. The arm has a full though often weak range of movement at the shoulder-joint, but there is pain with or without partial "locking" of a momentary nature during the middle phase of elevation, or when the arm is descending from the elevated position. This is the *painful arc* group, and the underlying pathology is a partial rupture of the supraspinatus tendon, an irritable area in the tendon due to inflammatory change, an exostosis at the tendon's humeral attachment, or a calcified nodule in the outer part of the tendon itself.
3. The arm cannot be moved actively or passively at the shoulder-joint at all—it is completely "stuck" or, as the Americans so aptly put it, "frozen." This is the *frozen shoulder* group, and the underlying pathology is an inflammatory change in the shoulder capsule.

Penicillin Nonad Tulle

*takes so
little time*

for, in a matter of seconds, it can be applied as a primary dressing round the finger following incision of a septic focus.

No need to prepare a dressing of penicillin ointment and gauze, no need to cut the dressing to the right size, Penicillin Nonad Tulle is designed in several sizes to suit a variety of requirements and the pieces 2 inches by 2 inches are a convenient size for use as a finger dressing.

Penicillin Nonad Tulle is the ideal bacteriostatic dressing to be applied to wounds infected with penicillin-sensitive organisms. The wide-mesh gauze is impregnated with an emulsifying base containing 1,000 i.u. of penicillin per gramme. The non-adhesive nature of the tulle encourages the formation of granulation tissue and ensures the easy removal of the gauze without disturbance of the newly formed tissue.

Penicillin Nonad Tulle is effective and easy to apply.

Useless Arm

The typical case occurs in a labouring man, usually over 45, who after a fall on the shoulder or after attempting to lift a heavy weight experiences sudden diffuse pain in the shoulder, with inability to elevate the arm or to hold it elevated when the examiner places it above a right-angle. A normal range of passive movement is always present on examination and usually tenderness can be found over the tip of the great tubercle of the humerus. The arm is useless, but the pain generally subsides in a few days or weeks. The disability is due to rupture of the supraspinatus tendon, so that there is loss of the power of fixation of the humeral head in the glenoid by the physiological hinge, and the deltoid is thereby put at such a disadvantage that, although it can be felt contracting strongly by the examining hand, it is unable to effect true shoulder movement.

In recent ruptures the loss of fixation may be no more than a reflex phenomenon produced by pain, since the other deep muscles—the subscapularis and the infraspinatus—often uninjured, are also thrown out of action. This can occur in incomplete recent ruptures just as readily as in cases in which the tendon has a complete tear across its substance. It follows, therefore, that it may well be impossible to distinguish clinically between complete and incomplete ruptures. If pain is abolished by injecting into the subdeltoid bursa a few millilitres of procaine, restoration of shoulder movement will occur in a few minutes in minor ruptures, but in complete ruptures the arm will remain as useless as before. This is a helpful test and easily carried out; helpful, because incomplete ruptures will heal without any special treatment apart from a period of rest, whilst complete ruptures will require surgery.

Treatment

Conservative measures are adopted in the first instance in all cases, and the arm is put at complete rest either in an abduction shoulder splint or else with the arm at the side in a sling or bandaged to the chest wall. There is some difference of opinion about the value of an abduction splint: personally I have not seen any advantage from its use and most patients complain of the awkward and uncomfortable position which it necessitates.

If there is return of some shoulder elevation within four to six weeks conservative measures can be continued and physiotherapy and exercises will complete the return of shoulder function. When no recovery of elevation has occurred in six weeks operation is advised, to repair the ruptured supraspinatus. Several types of rupture can be met with that require slightly different techniques for their repair, which need not concern us here. The aftercare consists of rest for the shoulder with the arm in a comfortable position—I do not now use an abduction splint—until pain and joint irritability have subsided, thereafter active exercises aided by hot packs and assisted movements from the masseuse.

It must be remembered, even though an apparently effective repair of the rupture has been carried out, that the prognosis in complete rupture is still far from perfect; this is especially true if the supraspinatus area shows marked degenerative change at operation. Surgical intervention is often followed by a "frozen shoulder," and it may be six to nine months before one knows

what the end-result is to be. This is particularly true in massive ruptures or avulsions of the capsule from the humerus; in these the outlook is extremely poor for the return of useful shoulder function.

Painful Arc

After a fall, or sometimes spontaneously, a painful arc of movement during mid-elevation of the shoulder develops, with weakness of movement which may be mild or may be so marked that the patient is unable to elevate the arm against the slightest resistance from the examiner. When the arm is at the side or in the fully elevated position no pain is felt and there is characteristically a full range of shoulder movement. The symptoms are often mild to begin with, and it may be many months before the patient seeks advice. Patients frequently state that one of their main worries is putting on an overcoat: often they require help with this but are able to carry out other shoulder movements without any difficulty. Sometimes, during elevation of the arm, momentary locking occurs. In time many patients develop trick methods of shoulder elevation to avoid the painful phase, and when both shoulders are examined from the back it often becomes clear that the rhythm of scapulo-humeral action is different on the two sides.

It is thought that the symptoms are due to impingement on the under surface of the acromion process of the outer part of the supraspinatus tendon where there is a tender area from rupture, a granulation tissue swelling, or a calcified nodule. This area is in contact with the acromion only during the middle range of elevation, and so during all other phases, when the two structures are apart, no pain is felt. It is known, however, that the supraspinatus reaches its peak of contraction normally between 80 and 120 degrees elevation of the arm, and it is conceivable that active contraction of this tendon, irritable from rupture or inflammatory change and accentuated by the pull of the tendons fused to it, may generate enough tension to be in itself sufficient to cause the typical pain.

Treatment

Here again conservative measures are adopted at first and consist in teaching the patient how to avoid if possible those movements which cause pain. Repeated injections of procaine into the subdeltoid bursa also help, but it is difficult to see how physiotherapy in any form can effect lasting change. About five out of every six cases eventually clear up whether "treated" or left to their own devices. The remainder should be treated surgically.

The operation is an exploration of the shoulder exactly as for ruptures of the supraspinatus, the acromion process being excised first of all. The supraspinatus area is then examined and when the exact pathological lesion has been identified appropriate surgical techniques are employed. These may consist in excision of a band of adhesions, excision of abnormal calcium deposit, repair of an incomplete tear of the tendon, or excision of an exostosis from the superior facet of the greater tubercle of the humerus. Since it is the impingement of the pathological area against the under surface of the acromion process which is the usual cause of the pain, it is clear that the most important step in the operative treatment is the removal of the acromion. This seems to cause no disability and little or no alteration in the

appearance of the shoulder except possibly in a very thin patient. The aftercare is similar to that described under ruptures of the supraspinatus.

Frozen Shoulder

Half of the cases in this group give a history of direct injury to the shoulder and in the other half the onset is spontaneous and more gradual. Women are affected twice as commonly as men, and the average age is 55 years. At the onset pain may be severe, almost continuous, and felt diffusely over the shoulder. It may radiate down the arm into the fingers, and is usually worse in bed at night. Later the pain becomes less and may only be felt on attempted movement of the shoulder, when it is typically experienced at, or close to, the insertion of the deltoid to the outer side of the humeral shaft. In the early stages all shoulder movements are lost, though, of course, the patient can elevate the arm to about 60 degrees by the gliding action of the scapula on the chest wall; this is, however, purely a scapular movement; true shoulder movement does not occur.

The shoulder gradually loosens, but a period of many months elapses in the average case before there is a return to full shoulder function. In a certain small percentage movement is permanently, though usually only partially, lost. In the average case wasting of the scapulo-humeral muscles can be seen or felt by palpation, though in fat patients this may be very difficult to demonstrate.

It is believed that the essential pathology in this group is inflammation of the capsule after injury or from irritative causes within the supraspinatus area itself such as calcium deposits or the degenerative process already referred to. During the early period of this inflammatory process exudation occurs into and around the capsule, so that fluid is present in the joint and subdeltoid bursa. Limitation of shoulder movement at this stage is mainly due to protective muscle spasm, which therefore relaxes under anaesthesia. When resolution of the inflammation occurs a replacement fibrosis may develop with the formation of adhesions around the capsule, so that there is still limited movement even when the muscles are relaxed under anaesthesia. It is therefore possible in most cases to distinguish between an irritative and an adhesive stage by the simple method of examination of the shoulder under anaesthesia. It is to be expected, of course, that some cases will be partly irritative and partly adhesive if an intermediate stage in the resolution of the inflammatory process has been reached at the time the examination is carried out. This is an important test which should be done in every case of "frozen shoulder," since in the irritative stage the treatment is by rest whilst the adhesive stage calls for active exercise aided by physiotherapy and manipulation. It is clear that in such a tendinous and avascular structure as the shoulder capsule the repair process will be slow and therefore the patient may have to suffer symptoms for many months.

Degeneration or rupture, especially central or partial rupture, of the supraspinatus area of the capsule may be followed by calcium deposition. Such deposits, requiring x-ray examination for their discovery, produce symptoms which are no different from those described above and under "painful arc." They are found in about 5% of any series and their presence is clear-cut evidence of degenerative change. Sometimes they set up by irritation a repair process sufficient to effect cure;

at others they may rupture into the subdeltoid bursa and produce an explosive onset of pain and uselessness of the arm for a week or ten days, rapidly followed by complete relief from all symptoms. The long tendon of the biceps in its passage through the front of the shoulder capsule may share in the capsular degenerative changes, and these may be so marked that eventually rupture of the tendon occurs.

Treatment

It is important to divide these cases into their subgroups of "irritative" or "adhesive," which, as previously pointed out, is best done by examining the shoulder under anaesthesia. In irritative lesions there is a full range of passive movements, whilst in adhesive cases movement is restricted though it can be freed by manipulation.

In irritative lesions treatment is primarily by rest, support of the arm in a sling being easiest for the patient. There are no real advantages in keeping the arm in an abduction shoulder splint; indeed, this often increases the pain. It has been customary to order heat in one of its various forms, but in a considerable number of cases this treatment may increase the pain and have to be stopped. If complete rest is given to the shoulder the severe pain gradually subsides in four to six weeks, and as soon as this occurs gentle exercises for the shoulder should be encouraged, aided if need be by massage. Exercises are best done while lying down on the back. In the average case return of function may be expected in three to four months, though it will not be full for eight months or even a year in the worst cases. If more vigorous measures are adopted the inflammatory process has no chance to subside and symptoms may persist for many months longer than is necessary.

In many cases replacement fibrosis occurs after the acute irritative stage has passed. At this stage pain is much less severe and usually occurs only on attempted movement. Whilst the shoulder is still "frozen" there is a little movement at the shoulder-joint, so that, along with the scapular glide, the arm can usually be elevated by the patient to about a right-angle. At this stage manipulation of the shoulder under anaesthesia is called for, when full movement can usually be obtained with palpable or even audible "snaps" which are due to adhesions breaking down. The manipulation must be carried out very gently, and, as a first measure, should be through full lateral rotation only. Often one manipulation is enough to free the joint, and it is usually found that after manipulation physiotherapy is a real help in hastening full recovery.

A few cases resist all conservative measures, and for these surgical exploration of the upper part of the joint should be advised, just as has been described for the preceding two groups. In these the subdeltoid bursa will usually be found to be obliterated wholly or in part by adhesions, and after excising the acromion process complete removal of the subdeltoid bursa and the adhesions will be necessary. Manipulation of the shoulder will bring the recesses of the bursa into view, and those adhesive areas which can be seen obviously to be limiting movement will be more readily demonstrated and their excision more accurately carried out. In not more than 5% the shoulder-joint remains permanently "frozen" despite careful conservative and operative treatment. In the other 95% the outlook is good.

THE TREATMENT OF THE OLDER PATIENT*

IT HAS RECENTLY BEEN SHOWN that the debilities of older patients may often be due not to age itself but to nutritional deficiencies. An increased intake of the deficient factors frequently re-establishes physical and mental health.

Bemax is an ideal supplement for this purpose. Important factors liable to be deficient—the B vitamins, protein and vitamin E—are all generously present in Bemax, and its easy digestibility makes them readily available to the ageing system.

* A special pamphlet on this subject has just been issued, and is available on request.

INSTANT HOT WATER —IN THE DOCTOR'S SURGERY

Doctors need hot water at irregular intervals, but when they want it they must have it at once. This need is met completely and economically by Ascot instantaneous gas water heaters. Every Ascot heater delivers hot water directly the tap is turned on and maintains the flow for as long as required—they never run cold.

Ascots are easy to install and economical in use—gas is consumed only while hot water is actually running. The boiling water heater (illustrated) is particularly suitable for the surgery. It delivers boiling water in less than a minute, and by the operation of a three-heat control will supply hot or warm water at will.

See this and other models at your local gas showrooms or send for descriptive leaflets.

VISITING CHILDREN IN HOSPITAL

BY

ALAN MONCRIEFF, M.D., F.R.C.P.

*Nuffield Professor of Child Health, University of London;
Physician, The Hospital for Sick Children, Great Ormond
Street, London*

AND

A. M. WALTON, S.R.N., R.S.C.N., S.C.M.

*Ward Sister, The Hospital for Sick Children, Great Ormond
Street, London*

This is a preliminary account of an experiment in visiting that seems to us to be so successful that we want to bring it to the notice of others. It is a plan for daily visiting of children, more particularly those of "toddler" age, by the mothers.

Working at various hospitals over a period of some years, we have been familiar with a variety of patterns for visiting. First may be considered the "no visiting" programme, with an exception made for dangerously ill children. This was probably based mainly upon a fear of introducing infection, but since the British Paediatric Association's investigation (Watkins and Lewis-Fanning, 1949) failed to show any correlation between visiting and cross-infection, this fear must be regarded as ill founded. (Visitors are still barred from infectious disease hospitals, in most instances, probably for fear of carrying infection out. Since doctors, nurses, domestic staff, and others in these hospitals "visit" the children and go into the outside world this reason seems a little illogical.) Whatever the reason, this system tended to produce unsatisfactory results. For the short-stay child it meant at least a few days of misery, followed often by a period of partial adjustment, and then, after going home—so we learnt not infrequently—a period of disturbance, although mother had been recognized and welcomed when the time came for discharge.

For children likely to be in hospital for long periods "no visiting" seems to produce the maximum of disturbance. The child forgets his mother, and clings to nurse when the time for discharge comes, so that his return home must be associated with great maternal distress, from the effects of which the child can scarcely escape. Moreover, it was not a satisfactory business for the nursing staff, who tended to develop a possessiveness with regard to the children, the eventual termination of which gave a psychological jolt to both parties.

A modification of the "no visiting" method is to permit parents to look at the children through a glass door or cubicle wall. If this allows the children to see the parents, even accidentally, it can only be condemned as cruel. Even when such accidents did not occur the parents were often very distressed. In wards where this was the custom there was frequent grumbling from nursing staff and from parents, and it never seemed satisfactory.

Daily Visiting

Visiting on "visiting day," once, twice, or even three times a week, is probably all right for older children, say, over 5 or 6 years of age. They can hold out for a few days, even a week, with the knowledge that "mum" is coming again then. For the younger children this is not possible. Their memories are short,

and their power of looking forward is short also. This led us to consider daily visiting as a solution. Before describing what in fact occurs it is worth while interpolating some remarks on visiting in general. So often, and not only in children's wards, it seems rather aimless. Mothers do not know quite what to do with the time. They are worried lest anything they do will upset the nursing staff. Therefore it did not seem to us sufficient just to allow visiting daily and leave it at that. The mother must be allowed and encouraged to do certain things to make the visit worth while to all concerned.

The present plan is that mothers are encouraged and even strongly urged to come daily between 5 and 6 p.m. They give the children their suppers, or they feed their infants. They read a story or play a game, clean teeth, hear prayers, and tuck the children down for the night. That is, they do in hospital the things they would do for the children at home. If tears threaten at the time of parting, the mother tries to stay until the child is asleep. If some children are not visited or a mother has to miss a night then some of the other mothers, who are familiar to the children, willingly lend a hand to act as a substitute. The child can look forward to to-morrow. When he first wakes, and for the earlier part of the day, it is not unexciting. New nurses, the doctor's visit, perhaps the visit of the occupational therapist, all help to pass the day, and if homesickness threatens, "mum" is coming after tea. The toddler can understand to-day and to-morrow and can associate things with a meal-time.

We believe that this daily hour spent together by mother and child helps to continue their relationship and does not break up the security which means so much at this young age. The child's needs are being satisfied jointly by mother and nursing staff without the development of abnormal possessiveness or transfer of affection. The mothers are less strained, because they have something to do. If there is some question they want to ask the doctor this is always arranged. (Although not directly associated with visiting, we believe the psychological strain for the parents of a sick child can be eased by making it possible for them to see the physician or surgeon in charge more or less on demand. A time is set aside at the end of each major ward round for this purpose. In fact, parents are encouraged to see the member of the visiting staff concerned and not to be content with what the nursing staff or resident medical officer has to tell them.)

The present method is, of course, supplementary to the presence in hospital of a nursing mother who is breast-feeding her baby. We have also made it a custom for mothers of babies who are artificially fed to come in for longer periods—namely, a day or so at a time—before the infant is discharged, so as to take over full responsibility for the child's care under supervision.

Some Difficulties

It would be unfair to pretend that there are no difficulties in the present scheme. The distance to be travelled daily by the mother, especially in a large city like London, may make daily visiting impossible. There may be other children in the family for whom supervision cannot be arranged. It has always seemed to us a weakness of the method, advocated by others, whereby mothers come in and look after their babies in hospital more or less entirely, that it ignores the rest of the family, especially perhaps the father. It is no gain

to the family relationship if, in saving the child in hospital some degree of psychological trauma, this is inflicted upon others in the family. The daily visiting method seems to share the mother between all those who have a claim on her without being unduly unfair on any.

The present scheme has been in operation for nearly 18 months. Mothers certainly like it. The nursing staff has an opportunity for closer contact with more of the mothers than is possible with any other method, and they also like it. The children seem happy, but clearly some form of follow-up and comparison with other methods is desirable. Children in hospital are part of the large group of children separated (temporarily) from their mothers and deprived of normal home life for a time. It is known that investigation of this larger problem is proceeding here and in other countries. A sponsored investigation of the narrower problem of visiting of children in hospital seems desirable. Meanwhile, without detailed knowledge of what exactly is going on in other hospitals we present this preliminary account of our own trials.

MEDICAL NEW YEAR HONOURS

The names of the following members of the medical profession were included in the New Year Honours List published in the *London Gazette* on January 1.

K.C.B. (Civil Division)

HAROLD PERCIVAL HIMSWORTH, M.D., F.R.C.P. Secretary, Medical Research Council.

K.B.E. (Military Division)

SAMUEL ROY BURSTON, C.B., C.B.E., D.S.O., V.D., F.R.C.P., F.R.C.P.Ed., F.R.A.C.P. Major-General, Australian Military Forces (ret.).

Knighthood

GEORGE VANCE ALLEN, C.B.E., M.D. Vice-Chancellor, University of Malaya.

WALTER RUSSELL BRAIN, D.M. President of the Royal College of Physicians of London.

RUDOLPH ALBERT PETERS, M.C., M.D., F.R.S. Whitley Professor of Biochemistry in the University of Oxford.

C.B. (Military Division)

RODERIC DUNCAN CAMERON, C.B.E., M.C., M.B., Ch.B., Major-General, late R.A.M.C. Honorary Surgeon to the King.

FREDERICK GEORGE HUNT, C.B.E., M.B., B.Ch. Surgeon Rear-Admiral. Honorary Physician to the King.

C.M.G.

JOHN CATARINICH, M.B., B.S. Director of Mental Hygiene, State of Victoria. 1937-51.

WILLIAM ARTHUR EDWARD KARUNARATNE, O.B.E., M.D., M.R.C.P. Professor of Pathology in the University of Ceylon.

C.V.O.

PETER JAMES KERLEY, C.B.E., M.D., F.R.C.P., F.F.R. Director, X-ray Department, Westminster Hospital.

ROBERT MACHRAY, M.B., B.S., F.F.A. Anaesthetist, Westminster Hospital.

C.B.E. (Military Division)

EDWARD ALFRED DALEY, M.B., B.S., F.R.A.C.P. Air Commodore, R.A.A.F. Honorary Physician to the King.

ALLAN WATT MCRORIE, M.D., D.P.H. Surgeon Captain, R.N. Honorary Physician to the King.

JOHN CONRAD NEELY, D.M., D.O.M.S., D.O., Air Commodore, R.A.F.

DENIS ADRIAN PRITCHARD, M.B., Ch.M., F.R.A.C.P., M.R.C.P. Surgeon Captain, R.A.N. Honorary Physician to the King.

WILLIAM KILPATRICK STEWART, A.F.C., M.B., Ch.B. Acting Group Captain, R.A.F. Director, R.A.F. Institute of Aviation Medicine.

C.B.E. (Civil Division)

CHARLES CAMERON, M.D., F.R.C.P.Ed., F.R.F.P.S. Professor of Tuberculosis in the University of Edinburgh.

CUTHBERT GAULTER MAGEE, F.R.C.P.Ed., Deputy Director-General of Medical Services, Ministry of Pensions.

M.V.O. (Fourth Class)

CHARLES EDWIN DREW, M.B., B.S., F.R.C.S. Chief Assistant and Surgical Registrar, Westminster Hospital.

PETER HENRY JONES, F.R.C.S. Senior Registrar, Brompton Hospital, London, S.W.

CYRIL FREDERICK SCURR, M.B., B.S., D.A. Consulting Anaesthetist, Westminster Hospital.

O.B.E. (Military Division)

JOHN ROBERTSON NIMMO, Major, R.A.A.M.C.

O.B.E. (Civil Division)

MURIEL HELEN DEEM, M.D. Medical Adviser to the Royal New Zealand Society for the Health of Women and Children (Plunket Society).

DONALD CHARLES FARQUHARSON, M.R.C.S., L.R.C.P. Regional Medical Officer, Ministry of National Insurance.

MANUEL LAZARUS FREEDMAN, M.B., Ch.B. Director of Medical Services, Bechuanaland Protectorate.

JOHN MCILRATH GIBSON, M.D. Medical Officer of Health and Chief School Medical Officer, Huddersfield.

ALFRED ERNEST HALLINAN, M.C., M.B., B.S. Regional Medical Officer, Ministry of Health.

WILLIAM ALEXANDER MILNE, M.B., Ch.B. For public and medical services in Greenock.

EDWARD GEORGE MONTGOMERY, M.B., B.Ch. Lieutenant-Colonel, late I.M.S., Surgeon-General, East Bengal, Pakistan.

ALFRED ARTHUR EDMUND NEWTH, M.B., B.S. Senior School Medical Officer, City of Nottingham.

VICTOR EMMANUEL PERERA SENEVIRATNE, M.D., M.R.C.P. Visiting Physician, General Hospital, Colombo.

GEORGE WRIGHT SIMPSON, M.D. Medical Officer and Chief Inspector of Physical Education, Scottish Education Department.

M.B.E. (Military Division)

ROBERT GOUDIE MACFARLANE, M.B., Ch.B. Major, R.A.M.C.

HAROLD STEWART MOORE, M.B., B.S. Lieutenant, R.A.M.C.

M.B.E. (Civil Division)

JOHN CAMPBELL ATHERLEY, M.B., Ch.B. Admiralty Surgeon and Agent, Manchester.

MURIEL JOSEPHINE LOUISE FRAZER, M.D., F.R.C.S.I., M.R.C.P. District Surgeon, St. John Ambulance Brigade, Northern Ireland District.

WILFRED BASIL RALPH JONES, M.R.C.S., L.R.C.P. Medical Officer, District I, Montserrat, Leeward Islands.

RONALD GREAVES LADKIN, B.M., B.Ch. Colonial Medical Service. Medical Officer, Uganda.

WILLIAM RICHARD LAWRENCE, M.B., Ch.B. Medical Practitioner of Te Aroha, Auckland, New Zealand.

An interesting new theory of taste is propounded in *Nature*, December 8, p. 977. It is based on histological study of the olfactory mucosa and taste buds of the rabbit, using new staining techniques which can display the localization of different enzymes, especially various kinds of phosphatases, in different cells. Sections of the nasal mucosa show that all phosphatases are concentrated in three or four basal cells in the olfactory epithelium, while lipases are restricted to Bowman's glands, but esterase is present in all the cells of the olfactory epithelium as well. In brief, a number of enzymes show sharp localization at one or more of six anatomical sites. This has suggested to the authors that substances which are tasted may inhibit the activity of an enzyme in one site, accelerate the activity of another in a second, and have no effect on enzymes in other positions. Inhibition and activation would alter the functioning of local nerve fibres, and thus create a distinctive spatial pattern of nerve impulses transmitted to the brain, and each pattern would represent a separate taste. A similar theory is proposed to account for smell.

and could find no appreciable difference. Baba (1946) studied the effect of intravaginal tampons on cervical erosions and vaginal discharges in 55 cases and concluded that, in the majority, their use had a favourable effect.

Genell and Lysander (1939) reported three cases of vaginitis which they attributed to the use of vaginal tampons. The report fails to give previous histories or the length of time the tampon was worn.

Present Investigation

This investigation was mainly concerned with the bacteriology of the vaginal flora following the use of the internal tampon. It was undertaken at the request of the visiting gynaecologists to the Elizabeth Garrett Anderson Hospital and with their co-operation. The object was to obtain information which could be given to patients, nurses, and doctors.

The original intention was to examine 100 volunteers over three monthly periods. Each volunteer was to undergo a pelvic examination by the gynaecologist before and at the end of the three months' use of vaginal tampons. In addition a vaginal swab was to be examined before and after each menstrual period for pH, bacteriology, and glycogen content, and to exclude any trichomonal or monilia infection.

Most of the volunteers were obtained from the gynaecological out-patient department, and, as many of these women were either fully employed during the day or were married, with young children, it was found impossible to get them to attend six times in three months. Thus in some cases a swab was taken before the first period and after three successive periods; but pelvic examination was made by the gynaecologist before and after completion of the study. Tampons were given to each subject, and complete instructions on their use were enclosed in each carton.

As these women were not quite normal, it was decided to enrol a number of normal women so that the results could be compared. I am indebted to Dr. Mary Barton for her co-operation, as she enlisted the help of a number of her patients, most of whom attended regularly over three months.

Since this investigation was started (over 13 months ago) 122 volunteers have been enrolled; 57 of these have completed three monthly periods or more, 17 have completed two monthly periods, and 26 have completed one monthly period; 22 have defaulted, 3 through failure to insert the tampon. In all, 100 volunteers completed one cycle or more. Six patients became pregnant.

Most of the volunteers were cases of infertility or dysmenorrhoea. A few had had small cervical erosions or complained of vaginal discharge. Only three of the cases showed a severe vaginitis; these are dealt with separately. Two volunteers were enrolled in rather unusual circumstances. The first reported at hospital thinking she had left a tampon in the vagina since her last menstrual period, over two weeks previously. This was incorrect. The second came with a complaint of offensive vaginal discharge, and on examination was found to have a retained tampon, which had probably been there since her last period three weeks before. In the hands of a careless person this is a possibility which is not likely to occur during the period, as the pad when saturated fails to fulfil its function, but, as quoted by Russell (1939), may occur at the end of the period.

All the volunteers were active women between the ages of 21 and 45 years. Eleven were single and 89 were married; 31 had not used tampons before; 69 had used them, but not all regularly.

The hospital patients suffering from cervical erosions or vaginitis were treated by the gynaecologists. Two swabs were taken on each occasion by rotating the swab round the anterior and posterior wall in the upper part of the vagina. One swab was used for estimating the pH by means of Johnson's pH papers, and then immersed in normal saline and incubated for a short time to be examined for monilia or trichomonads. The other swab was used for aerobic and anaerobic culture, and films were made for Gram stain and glycogen estimation. The glycogen content was examined by the method recommended by Siegler (1944), and was recorded as a percentage of the epithelial cells containing glycogen.

Bacteriology

Of the 100 volunteers, 63 showed no pelvic abnormality and were regarded as normal for the purposes of this study. One volunteer attended regularly for 10 menstrual periods, two for seven periods, and the rest for periods varying from one to four in number. The predominant organism found in the direct smear from 57 cases in this group was Döderlein's bacillus. The cultures gave a mixed growth of Döderlein's bacillus, coagulase-negative *Staphylococcus albus*, diphtheroid bacilli, and, occasionally, coliform bacilli. The bacteriology was very similar in the pre- and post-menstrual cultures. The remaining six volunteers in this group had an abnormal flora: four showed the presence of *Candida albicans* in direct smear and on culture, one had a persistent growth of a coliform bacillus associated with *Streptococcus faecalis*, and the sixth developed a trichomonal infection with vaginitis. The last-mentioned patient developed an irritating vaginal discharge one week before her second menstrual period, due to *Trichomonas vaginalis*. This was a recurrence of a previous infection. It cleared very quickly with acetarsol pessaries, and did not recur after her next menstrual period.

The four patients with *C. albicans* had no signs or symptoms of vaginitis (yeasts are sometimes found in the healthy vagina), and responded well to "mycil" pessaries in two cases, the flora returning to normal after treatment. The other two cases were not treated, and the infection was uninfluenced. The volunteer whose cultures gave a growth of a coliform bacillus showed no signs of vaginitis or cervicitis, and the flora remained abnormal throughout the investigation. In order to compare the results, post-menstrual swabs were taken from a number of normal young women who used the perineal pad for protection. The bacterial flora thus obtained showed no marked variation from that obtained in the tampon series.

The other 37 volunteers showed some evidence of pelvic disease. Thirty-three had a cervical erosion or showed signs of vaginitis, two had a minor degree of prolapse, one a cystic ovary, and another a fibroid uterus. The majority of the erosions were small and did not require treatment. The larger ones were cauterized at the beginning of the investigation, and some of them were subsequently painted with "negatol" 100%. Three cases, summarized below, showed a severe vaginitis. The bacteriology in the cases of simple erosion corresponded to a normal flora in 20 cases and an abnormal

flora in 10. Of the latter four showed *C. albicans* on smear and culture, one *Tr. vaginalis*, and two coliform bacilli and *Str. faecalis*. The three others have been classified as severe vaginitis. Three of the cases of infection with *C. albicans* were treated; owing to illness the fourth attended during one menstrual period only. Two of the cases responded to treatment, and the infection did not reappear during the investigation. The fourth case did not respond to treatment: this patient had been attending hospital for several months with a chronic vaginitis, and her condition was uninfluenced by the use of vaginal tampons. One negative swab followed treatment of the trichomonal infection with acetarsol pessaries, but the infection recurred six weeks later, after an illness. She was then treated with acetarsol impregnated tampons, and the vaginitis cleared up completely; it had not recurred two months later.

The vaginal pH of the cases varied from 4.2 to 5.4, but showed no marked difference in the post-menstrual period.

The glycogen content of the epithelial cells remained fairly constant in all cases. It was normal in some throughout, and low in others, especially in cases of infertility, but was uninfluenced by the use of the tampons.

Case Reports

The following is a summary of the three cases of severe vaginitis mentioned above in which vaginal tampons were used during the menstrual periods, over three months in Cases 1 and 3 and two months in Case 2.

Case 1.—This patient, aged 30, had used vaginal tampons for one year. She complained of an irritating vaginal discharge of one week's duration. Examination revealed a purulent discharge, with severe vaginitis but no erosion. The wet film from the pre-menstrual swab showed many pus cells, hyphae, and spores of monilia. Culture yielded a growth of *C. albicans*, a coliform bacillus, and *Str. faecalis*. The *albicans* infection responded to mycil pessaries, but the coliform infection was still present at the end of the second menstrual period. This was treated with "sulphatriad" pessaries for 10 days, and when the patient returned for her third pre-menstrual swab 11 days after her last treatment the flora had returned to normal, and remained so in her post-menstrual swab. A vaginal examination at this time showed that the vagina and cervix were healthy, and the patient was discharged.

Case 2.—The patient, aged 23, had used vaginal tampons regularly. She complained of an irritating offensive vaginal discharge of three weeks' duration. On examination per vaginam a retained tampon was found which had caused severe vaginitis and a cervical erosion. Unfortunately a swab was not taken. She was advised to douche and return in one week's time. She did not return until 14 days later, as her menstrual period had occurred, during which she had used vaginal tampons. Her discharge was then less offensive, and the vaginitis had abated. A swab taken, yielded a mixed growth of a coagulase-positive *Staph. aureus*, coliform bacilli, and *C. albicans*. Treatment consisted of ichthyol and glycerin pessaries and douching. Three weeks later her pre-menstrual swab showed a scanty growth of *C. albicans*, but on examination there was no evidence of vaginal thrush. The post-menstrual swab one week later showed a normal flora. The vaginitis was much improved, the erosion had practically healed, and she had no complaints. Unfortunately this investigation finished at that time, but she was advised to return if her symptoms recurred. She had not done so three months later.

Case 3.—The patient, aged 42, had used vaginal tampons regularly. She complained of excessive loss at periods and vaginal discharge. Examination per vaginam showed a

cervical polyp and cervical erosion with vaginitis. The polyp was removed and the erosion cauterized. Two months later this patient volunteered for the investigation. A large erosion was still present. A pre-menstrual swab yielded a growth of a coagulase-negative *Staph. albus* and *Bact. coli*. The erosion was painted with negadol 100%. Her second post-menstrual swab yielded a moderate growth of a coliform bacillus, but on examination the erosion was healing and smaller in size. The third post-menstrual swab showed a normal flora, and the erosion was almost healed.

These three cases responded to active treatment during the three months' investigation. Their progress compared very favourably with four similar cases in which the perineal pad had been used for protection.

Discussion

The principal organism associated with the healthy vagina is a pleomorphic non-sporing Gram-positive bacillus, variably anaerobic, identified by Döderlein in 1892. The vaginal flora found in the healthy adult is mixed, and staphylococci, enterococci, coliforms, and diphtheroids are also present (Wilson and Miles, 1946). Three grades of "cleanliness" are generally recognized in the vagina of the adult, and the classification of Heurlin (1941) is the one most usually accepted (Baird, 1950).

Grade 1.—Many epithelial cells, an occasional leucocyte, many Döderlein bacilli, and hardly any other organisms; pH 4-4.6.

Grade 2.—Pus cells in excess of epithelial cells, few Döderlein bacilli, and a mixture of diphtheroids, cocci, and coliforms; pH 4.5-6.

Grade 3.—Many pus cells, a few epithelial cells, no Döderlein bacilli. A host of other organisms—Gram-positive and Gram-negative cocco-bacilli, coliforms, Gram-positive bacilli, comma bacillus, and others; pH above 6.

Heurlin mentions 37 varieties of bacteria which find their natural habitat in the genital tract. Many of these are saprophytic, and are seen only in direct smear. This may be accounted for by the bactericidal action of the vaginal secretion. With such a variety of organisms found naturally, the criterion adopted for the normal in this study has been the preponderance of Döderlein's bacillus found in smear and on culture; the criterion for the abnormal has been the excess of pus cells and organisms other than Döderlein's.

The organisms found in the post-menstrual cultures of the normal volunteers (63 in number) corresponded mainly to the Grade 1 flora. No appreciable difference was found in the bacterial flora of the pre- and post-menstrual culture. Döderlein's bacillus was the predominant organism in the direct smear, and grew well on culture, especially under anaerobic conditions. It was frequently associated with a coagulase-negative *Staph. albus*, and occasionally with diphtheroid bacilli and a scanty growth of coliform bacilli. Grade 2 flora was found in five cases, four of which showed a monilia infection on culture, and the fifth had a recurrence of a chronic trichomonal infection. In these five cases the pus cells were in excess of the epithelial cells, but in three of them the flora returned to grade 1 after treatment; in two untreated cases it was unaltered.

The bacteriology of the 33 cases with cervical erosions or vaginitis corresponded to grade 1 (20 cases) and grade 2 (10 cases). Three cases of severe vaginitis showed a grade 3 flora.

An anaerobic streptococcus was found on several occasions, but this organism is a normal inhabitant of

the vagina (White, 1933). One strain was sent to the Streptococcal Reference Laboratory at Colindale, and the following report was received: "The streptococcus produced an α -haemolysis, was not heat-resistant, did not belong to any of the Lancefield groups, and formed no mucoid colonies on sucrose agar. It could not be identified."

The anaerobic streptococcus isolated by White was a strict anaerobe, and very slow-growing, requiring two to four days' incubation. None of these organisms was isolated, probably because the cultures became overgrown by contaminants if incubated longer than 48 hours. No gas was formed by any of the anaerobic streptococci, mannite was not fermented, the organism did not grow on MacConkey's medium, and there was no evidence that this organism was pathogenic. *Str. faecalis* was found in association with coliforms on three occasions. In one case the cervix and vagina appeared healthy.

Ten cases were found to have *C. albicans* on culture; only four of these had a vaginal discharge or showed evidence of vaginal thrush. Six cases had no symptoms. Two volunteers had a trichomonal infection: one was a recurrence of a previous infection during the period under study, but it cleared up very quickly with acetarsol pessaries, and did not occur after the next menstrual period. The other was a recent acute infection. None of the other volunteers acquired monilia or trichomonal organisms during the period of study or developed erosions or vaginitis as a result of using the internal tampon.

Erosions

The findings have already been summarized. There was no aggravation of the condition or delay in healing following the use of tampons in the patients who had cervical erosions. All the erosions were reduced in size if not completely healed, and the bacterial flora, where abnormal, had returned to normal at the end of the period under study. The vaginal tampon, when properly used, is not in contact with the cervix but only with the vaginal wall, which is self-protecting (Cruikshank and Sharman, 1934). Three cases had signs of severe vaginitis and one of them had a large erosion, the vaginitis in one case being caused by a retained tampon. They were medically treated by the gynaecologist, and all continued to use tampons for protection. In each case the underlying cause responded to treatment, and did not recur, which proves that the internal tampon does not act as an irritating foreign body. All had a grade 3 flora at the beginning of the study; this reverted to grade 1 at the end. The rate of healing compared favourably with four control cases in which the perineal pad was used.

The glycogen content was estimated as a percentage of the epithelial cells in the smear containing glycogen. It was found to be low in some cases of infertility, but was uninfluenced by the use of tampons. Normally most of the epithelial cells should contain glycogen.

The pH was less acid than the normal grade 1 flora in some of the patients, probably owing to the fact that the swab was taken from the upper part of the vagina, to avoid contaminants found in the lower part. There was no appreciable alteration in the pH in the pre- and post-menstrual phases.

The volunteers who had not previously used tampons stated that they were comfortable to wear and did not cause the irritation usually found with the perineal pad.

A few complained that they did not give enough protection at the beginning of the menstrual period, and that a perineal pad was required as well. There were no complaints of an excessive flow of blood on withdrawal, of difficulty in removal, or of any odour associated with their use. The average number employed in one cycle was ten. Two volunteers stated that they required 15-18 tampons.

Summary

A series of 100 women used vaginal tampons for protection during the menstrual period over three to ten successive periods in 57 cases, two-monthly periods in 17 cases, and one-monthly period in 26 cases. Smears and cultures taken before and after each period showed no appreciable change in the bacterial flora of the vagina.

A study was made of 33 unselected cases of cervical erosion or vaginitis in which internal tampons were used. Healing of the erosions was not adversely affected; it compared favourably with a control series using the perineal pad. In three of the cases the bacterial flora corresponded to grade 3 at the beginning of the study, but returned to the normal grade 1 at the conclusion.

There was no evidence of local irritation or inflammation caused by the use of internal tampons. No appreciable alteration in the vaginal pH or in the glycogen content of the epithelial cells was noted. A retained tampon may cause damage to the vagina or cervix, and patients should be warned to remove the soiled one before inserting a fresh one. Removal is particularly important at the end of the menstrual period.

There was no evidence that vaginal tampons are prejudicial to health.

My thanks are due to the gynaecologists of the Elizabeth Garrett Anderson Hospital, in particular to Miss Josephine Barnes for her great help and encouragement throughout the study, and for her most useful criticism of this paper. Tampax Limited aided the research work by a grant, and supplied the tampons.

The Ministry of Health is lifting the 21-year-old ban on importing parrots, as from January 8. The regulations have been revoked because there has been no significant recurrence of psittacosis in this country since the worldwide outbreak which led to the ban. Furthermore, research has since shown that psittacosis, which was originally believed to be confined to the parrot species, also occurs in seagulls, pigeons, ducks, turkeys, and similar birds. Moreover, modern drugs, such as penicillin and the new antibiotics, have largely robbed the disease of its dangers. Only one death has occurred in England and Wales in the last 10 years. The lifting of the ban does not affect any other legal requirements. For example, anyone importing a parrot from certain countries will still need a Board of Trade licence to import a seed-eating bird.

A T-PIECE TECHNIQUE FOR GENERAL INHALATIONAL ANAESTHESIA

A SAFE METHOD OF REDUCING OPERATIVE BLEEDING

BY

JOHN BULLOUGH, M.B., B.S., M.R.C.S., D.A.
Visiting Anaesthetist to Ormskirk County Hospital and
Southport General Infirmary

Anaesthetists are interesting themselves in the reduction of operative bleeding. One of numerous possible angles from which to attempt this—the lowering of the patient's arterial blood pressure—has received attention recently. To what extent this procedure may safely be applied remains to be seen. The object of this article is to draw the attention of anaesthetists to a simple technique of inhalational anaesthesia which, among other advantages, safely reduces operative bleeding, and, coupled with the intelligent use of posturing the patient, makes the use of drugs to lower the arterial blood pressure unnecessary on most occasions, since such bleeding as does occur is insufficient materially to influence the surgeon's operating conditions.

The technique described is a development of the T-piece technique of Ayre (1937a, 1937b), which was intended, among other things, to reduce vascular congestion during operative surgery. My technique differs from Ayre's in several respects: no additional apparatus is required, endotracheal intubation is unnecessary but may be used, nitrous oxide is the main agent used, air is excluded from the inhaled mixture, only minimal quantities of the volatile agents are used, a change to a semi-closed circuit can be accomplished in a matter of seconds, and the passage of gases through the "T" is different.

Ayre's Technique

Ayre's T-piece technique is briefly as follows. The apparatus consists of a series of tubes for the passage of gases connected together by a small T-shaped metal junction. A small flow of oxygen (2 litres a minute) carrying a high concentration of ether vapour is passed from an anaesthetic machine along some narrow-bore tubing through the vertical limb of the T junction into the horizontal limb (see Fig. 1). The proximal part of the horizontal limb is connected to an endotracheal tube through which gases enter the patient's lungs; the

FIG. 1.—Ayre's T-piece technique.

distal part is connected to a short length of wide-bore tubing which is open to the atmosphere. This part of the apparatus forms a small reservoir for oxygen, ether vapour, and gases from the last expiration. The degree of rebreathing can be controlled by varying the length of this distal piece of tubing. Thus expiratory valves and rebreathing-bags are dispensed with; the patient breathes oxygen, ether vapour, and air, at atmospheric pressure, with negligible resistance to inspiration or expiration. Resistance to expiration is a potent source of vascular congestion, and thus of increased operative bleeding. The only other available methods of inhalational anaesthesia which eliminate resistance to breathing are true "open-mask" techniques and insufflation techniques, both of which have distinct disadvantages which make them inferior to the T-piece technique.

Ayre's technique is probably unsurpassed as a method of inhalational anaesthesia for operations on small children about the head and neck; it has, however, a number of disadvantages which may account for its being seldom used for other types of operations. The disadvantages are: (1) Additional apparatus is required. (2) Some anaesthetists find that fitting the apparatus together is tedious. (3) Endotracheal intubation is necessary, and may not be justifiable for a minor type of operation. (4) A change to other techniques cannot readily be made. (5) Artificial respiration by inflation of the lungs cannot readily be achieved. As relaxant drugs are so commonly used, a means of inflating the lungs is often necessary. (6) Relatively large quantities of ether are required to maintain anaesthesia, as the vehicle is a mixture of air and oxygen. (7) There is an explosion hazard.

The following technique overcomes all these disadvantages and enables the T-piece principle to be used for any type of operation and any type of patient.

Modified Technique

The T in this technique consists of two large-bore lengths of corrugated tubing connected together by a large-bore metal T junction (on which is mounted an expiratory valve), as supplied as standard apparatus for any circle-type absorption unit. At the distal ends of

FIG. 2.—Modified T-piece technique, using endotracheal tube. The corrugated rubber tubing is shown as about one-third its correct length.

FIG. 3.—Modified T-piece technique, using facemask.

the rubber tubing are metal connexion-tubes. A mask, or endotracheal adaptor, is connected in the usual place. A high flow of fresh gases, 8 litres a minute, is passed through the apparatus; it consists of 75% (6 litres) nitrous oxide and 25% (2 litres) oxygen, with the vapours of any volatile anaesthetic agents as required (see Figs. 2 and 3). The two lengths of corrugated tubing form the horizontal limb of the T in this technique, and the patient takes gases from it via the vertical limb, which consists only of the facepiece mount; the passage of gases is thus somewhat different from that obtaining in Ayre's technique.

In practice, Boyle's apparatus is used as follows. The single corrugated tubing is detached from the usual semi-closed unit (Magill unit) at the junction just distal to the reservoir bag, and in its place, at this point, one end of the double-hosing unit is plugged in. A facepiece is attached in the usual place, and the other end of the double-hosing unit is left open to the atmosphere. The apparatus is now ready for use.

Boyle's apparatus fitted with a Coxeter-Mushin absorption unit can be used as above, or in a simpler way. The Coxeter-Mushin unit is in use, shall we say, as a semi-closed circuit, the soda-lime is turned off, the rebreathing dial is set at 50%, and 6 litres of nitrous oxide and 2 litres of oxygen are flowing, the anaesthetic being administered through either a facemask or an endotracheal tube. Now, if the hosing on the expiratory side is disconnected from the absorption unit and the open expiratory port plugged with gauze or a cork, the T-piece principle is in action. It is not necessary to alter the rebreathing control, as rebreathing cannot take place into the reservoir bag on account of a gravity valve on the inspiratory side. This valve is kept open by the high flow of fresh gases, and thus does not form any obstruction to inspiration in this technique. A small amount of fresh gases tends to accumulate in the bag, which is a desirable thing.

A Marrett apparatus can be converted in the same way, and a metal stopper is supplied with the apparatus for insertion into the expiratory port, though it is supplied for another reason. When the Coxeter-Mushin or Marrett apparatus is in use a change to conventional circuits is made by reversing the procedure, which takes only a few seconds. When Boyle's apparatus is in use a change to a semi-closed circuit is very simply made, by covering the open end of the hosing with the hand, the expiratory valve on the T junction being partly open. In either case manual inflation of the lungs is readily achieved.

By this technique air is prevented from entering the patient's lungs by the high rate of flow of fresh gases and the large volume of gases in the apparatus, which exceed the patient's minute-respiratory volume and his tidal exchange respectively, as the physics of the matter will show.

Physics

The volume of gas contained in the double rubber hosing unit is about 600 ml.—300 ml. on each side of the T junction. Let us suppose that the patient is breathing fifteen times a minute, and that his tidal volume (exchange) is 500 ml., a common occurrence when this technique is in use. His minute-respiratory volume is 7,500 ml. With a flow of 8 litres of fresh gases a minute, the patient's minute-respiratory volume is exceeded, and so no carbon dioxide can accumulate in the apparatus

except under the facemask. This can be ignored except when the patient is a very small child or when the tidal exchange is greatly reduced.

A flow of 8 litres of fresh gases a minute equals 133 ml. a second, or 532 ml. in four seconds. With a respiratory rate of fifteen a minute, the patient inspires once every four seconds. During these four seconds 532 ml. of fresh gases have entered the apparatus, and so the patient inhales 250 ml. of fresh gases from the inspiratory side of the rubber hosing from the reservoir bag, and 250 ml. of gases from the expiratory side of the rubber hosing, consisting partly of fresh gases and gases from his last expiration. In order to draw air into his lungs the patient will need to take a considerably deeper breath, for there is the dead space under the facemask, about 50–100 ml., and his own anatomical dead space, 150 ml., intervening between his lungs and the atmosphere. If, however, there is no reservoir bag on the inspiratory side of the apparatus the patient will take about 100 ml. of fresh gases direct from the flowmeters, 300 ml. of gases from the expiratory side of the hosing, and the remainder of his inhalation will be air. This would be a similar state of affairs to that in Ayre's technique.

A measure to prevent the entry of air into the lungs in this event, or if the patient is breathing too deeply, is to attach a further length of hosing to the expiratory side, in the shape of the single rubber hosing from the Magill unit which may be lying idle. It is important not to allow any air to enter the patient's lungs, otherwise the potency of the inhaled mixture is considerably weakened, as it is mainly nitrous oxide that is maintaining anaesthesia in this technique.

Clinical Application

In practice it is advisable to get the patient well settled by another technique before applying the T-piece principle, so that breathing is quiet and regular. For an adult intravenous thiopentone is excellent; for a small child an open-mask technique may be used. If an open-mask or semi-closed technique is used for the induction a quietening in the patient's breathing accompanied by a reduction in the amount of operative bleeding will usually follow the change over to the T-piece technique.

As an illustration of the technique, this would be the anaesthetic procedure for an operation such as a mastectomy. Premedication need only be light, with the customary doses of morphine and atropine, or "omnopon" and scopolamine. Induction takes place in the anaesthetic room with intravenous thiopentone, 0.25–0.5 g. being used as required; the syringe is left in place or a Gordh attachment is fitted to the needle. The patient is now transferred to the operating table. To get the patient settled further intermittent injections of thiopentone are given until he has received, say, 0.75–1 g. This will produce about ten minutes of surgical anaesthesia and a basal level of narcosis for about an hour in an average patient. During this initial period of ten minutes the patient will have been placed in position for operation, the diathermy pad applied, the skin prepared, the towels fixed, and the inhalational anaesthetic and operation started.

The facemask is applied as soon as convenient, with 6 litres of nitrous oxide and 2 litres of oxygen running. This concentration of nitrous oxide may be sufficient to maintain a very light plane of anaesthesia in some patients following the drugs previously given, but other agents will usually be required to prevent reflex response

to operative stimuli, such as movements of the limbs or face, laryngeal activity, respiratory changes, rise in pulse rate, and other phenomena. Any desired supplement may be used, according to the preference of the anaesthetist, such as low concentrations of trichlorethylene ("trilene"), "vinesthene," ether, or even cyclopropane (100–200 ml.); alternatively, further intermittent injections of thiopentone or injections of pethidine may be given. If trichlorethylene or ether is used it is only necessary to raise the lever of the Boyle's bottle to the top of the second division, plunger up. Changes in cardiac or respiratory rhythm are extremely rare when trichlorethylene is used, and this is probably the most useful supplement, as it is non-explosive and has a very potent analgesic action.

Should the patient's tidal exchange become inadequate for his metabolic requirements some degree of cyanosis will usually follow if his blood haemoglobin is normal, since the concentration of oxygen in the inhaled mixture approximates to that of atmospheric air: this is a safeguard against carbon dioxide accumulation in the patient which may follow shallow breathing—another common cause of increased operative bleeding. Cyanosis may be remedied by one of several methods: by increasing the rate of flow of oxygen or decreasing the rate of flow of the nitrous oxide, by adding 500 ml. of carbon dioxide to the flow of gases, by changing to a semi-closed circuit, and by assisting respiration by bag-pressure. These measures should not, however, be prolonged, as they will detract from the benefits of the technique, particularly as regards the quantity of operative bleeding.

Should the patient's breathing become too deep there will be a danger that air may enter his lungs, which will in turn be followed by a rapid lightening of anaesthesia, so that immediate action is called for. An injection of thiopentone will usually have the desired effect, but if this is not possible the flow of nitrous oxide should be raised temporarily to 8 litres, the concentration of supplementary agent increased, or perhaps an injection of pethidine made. If the depth of breathing is not soon decreased it is advisable to change to a semi-closed circuit until the patient comes under control, lest he should return to consciousness. The addition of a second length of rubber hosing to the expiratory side of the apparatus will also help to prevent entry of air into the lungs.

A rather useful point about this technique is that, by the simple expedient of applying the open end of the rubber hosing to his ear, the anaesthetist is able to listen to every breath that the patient takes; thus positive proof is continuously available that the patient is breathing adequately through a clear airway, or otherwise, as the case may be. This should be very useful during intracranial operations.

The technique has the disadvantage that comparatively large quantities of gases are used; but then these are very cheap compared with intravenous drugs. There is also the inconvenience of changing cylinders. Body heat and water vapour are lost by the patient to the atmosphere; but this loss is a totally normal occurrence, and is no greater than in normal breathing, and can scarcely be said to be harmful.

In addition to the advantages already mentioned, this technique makes the use of nitrous oxide and oxygen, with truly minimal quantities of supplementary agents, a practical proposition when the patient is a small child, and it has been safely and satisfactorily used on patients

as young as 1 year old. This is perhaps because there is the minimum of interference with normal physiological breathing. In this respect the technique compares favourably with open-mask techniques, and is recommended to those anaesthetists whose surgical colleagues insist on the use of "open ether" for such operations as thyroidectomy.

Summary

The use of the T-piece principle of inhalational anaesthesia is offered as a safe and satisfactory method of reducing operative bleeding.

Ayre's T-piece technique is briefly described and its disadvantages are mentioned.

A technique which overcomes these disadvantages is described.

An account is given of two simple ways of converting standard apparatus to the T-piece principle. No additional apparatus is necessary, but endotracheal intubation may be used. Nitrous oxide is the main agent; air can be excluded from the inhaled mixture. A change to or from a semi-closed technique can be accomplished rapidly.

The technique may be used for adults or children, and for any type of surgical operation.

The applied physics of the technique is outlined.

As an illustration, a typical anaesthetic for a patient undergoing a mastectomy is described.

Medical Memorandum

Leukaemia With Primary Gynaecological Manifestations

Although leukaemia in association with pregnancy has been reported and discussed in many recent papers, a search of the *Quarterly Cumulative Index Medicus* shows no report in recent years dealing with leukaemia from the gynaecological aspect. Therefore the admission to one hospital of three such cases as acute gynaecological emergencies in a short period appears to be worthy of record.

Case 1

An unmarried woman aged 22 was admitted on April 17, 1947, at her doctor's request as a case of pneumonitis complicated by abortion. She stated that she had had a cough all her life, that it had been worse for the past month, with pain in the right side of the chest, night sweats, but no sputum. Menstruation had always been normal and regular, but she had bled severely from the uterus for seven days preceding admission to hospital.

She was pale, weak, and very ill. Her blood pressure was 130/60. A faint macular eruption was present on both legs, from the thighs to the ankles. There were signs of consolidation at the right base of the lungs, and the tip of the spleen was just palpable. On rectal examination the cervix and uterus appeared to be normal. An immediate blood count was as follows: red cells, 2,350,000 per c.mm.; Hb, 40%; C.I., 0.79; blood group, A; white cells, 1,075 per c.mm. (polymorphs 33%, lymphocytes 64%, monocytes 3%); platelets very scanty; nucleated red cells, 25 per 100 white cells; bleeding time 10 minutes (normal by method used 1–2 minutes). A film of sternal marrow was reported as showing "great reduction in white blood cells; only a few polymorphs and myelocytes seen in many fields. There are a fair number of nucleated red cells of rather early

type." X-ray films of the chest showed "consolidation of lower portion of right upper lobe." Sputum report: "No tubercle bacilli seen in three specimens." Culture: "*Staphylococcus aureus* and *Micrococcus catarrhalis*."

Repeated blood transfusions caused no change in the blood picture, each transfusion appearing to restart uterine bleeding. On May 26 a complete left-sided facial palsy developed. On June 13 x-ray examination showed complete resolution of the consolidation in the right lung. On June 14 the blood picture suddenly changed: red cells, 5,360,000 per c.mm.; Hb, 82%; white cells, 292,000 per c.mm. (neutrophil polymorphs 3%, eosinophils 1%, lymphoblasts 4%, myeloblasts 92%); a few nucleated red cells present; platelets very scanty.

Treatment was started with urethane, but on June 25 there was complete nasal obstruction from oedema and haemorrhage into the nasal mucous membrane, haemorrhages into both conjunctivae and the soft palate, and considerable enlargement of all the groups of glands in the neck. The patient died on July 7. A post-mortem examination was refused.

Case 2

A housewife aged 40 was admitted on September 2, 1948. She was sent to hospital with a letter from her own practitioner which stated: "Please admit. Severe uterine haemorrhage for five months. Confined nine months ago." She was seen by the gynaecological registrar, who reported: "Looks pale, thin, and ill. Abdomen N.A.D.; a few small glands both groins. P.V.: heavy loss. Cervix soft and patulous, feels and looks quite healthy. Uterus soft, bulky, and antverted. Fornices clear. May be incomplete abortion, or placental polypus, or chorionepithelioma. For diagnostic dilatation and curettage when general condition better."

She was admitted to a ward, where a general examination showed no abnormality, except that the tip of the spleen was just palpable. A blood examination was made and the report was as follows: red cells, 900,000 per c.mm.; Hb, 22%; platelets very scanty; white cells, 8,200 per c.mm. (polymorphs 7%, lymphocytes 37%, myelocytes 3%, myeloblasts 53%). Sternal puncture: myeloblasts, 75%; neutrophil myelocytes, 9%; eosinophil myelocytes, 7%; polymorphs, 5%; eosinophils, 1%; basophil normoblasts, 3%; polychromatic normoblasts, 2%.

Repeated blood transfusion and deep x-ray therapy were given. The patient went home at her own request on October 6. She gradually deteriorated and died about three months later.

Case 3

An unmarried woman aged 22 was admitted on April 1, 1949, as a case of "uterine haemorrhage with slight haematemesis." On admission she said that her menstrual period had begun 14 days previously and had continued ever since. She had always bruised easily. One week before the onset of the last period her gums had bled; this was followed by an abscess in the region of the upper left molar teeth which had subsided after penicillin injections. She had started to vomit small flecks of blood-stained material on the morning of the day of admission. Further, she had previously attended two other hospitals for severe dysmenorrhoea with excessive blood loss. One of these hospitals informed us that in March, 1946, her haemoglobin had been 94%, white cells 7,000 per c.mm., with a normal differential count. The other said that in January, 1947, she had had a haemoglobin of 104%.

She was pale, with a marked gingivitis. The lungs, abdomen, and central nervous system showed no abnormality. There was a harsh systolic murmur in all the cardiac areas. A blood examination was made immediately on admission: Hb, 40%; white cells, 28,800 per c.mm. (polymorphs 20%, lymphocytes 12%, metamyelocytes 2%, myelocytes 6%, myeloblasts 60%); nucleated red blood cells, 6 per 100 white blood cells; platelets very scanty. Sternal puncture confirmed the picture of an acute myeloblastic leukaemia.

Repeated blood transfusions and urethane were given, and, although the white-cell count dropped to 8,800 with only 5% myeloblasts, the clinical course was one of steady deterioration, with haemorrhages in the optic fundi and large haemorrhages all over the body. She died five weeks after admission.

At necropsy the spleen was of normal size, the liver large and infiltrated, and the bone marrow everywhere replaced by a soft pink material.

Comment

Most textbooks of haematology and of gynaecology make but brief reference to the possibility of leukaemia as a cause of uterine bleeding. Thus Whitby and Britton (1946) state regarding leukaemia, "Multiple haemorrhages in the retina, ear, spinal cord and brain, or from the uterus, kidney, or bowel, may all be found," but state, further, that "in myelocytic leukaemia, amenorrhoea or scanty menstruation is common." Moore White (1944) says: "Uterine haemorrhage may be a symptom of most of the blood diseases." Browne (1950) comments more fully: "Such blood diseases as splenic anaemia, idiopathic hypochromic anaemia, aplastic anaemia, leukaemias, and thrombocytopenic purpuras may be associated with menorrhagia. Secondary thrombocytopenia arising from malignant neoplasms, leukaemia, septicaemia, arsenical poisoning, and x-ray or radium therapy may so depress that bleeding time is prolonged and menorrhagia may occur." It is to be noted that in all three cases described the platelets were very scanty. Several other standard textbooks consulted make no reference to the possibility of uterine haemorrhage being caused by leukaemia.

This hospital, being one of the former municipal hospitals of London, has always received large numbers of cases of uterine haemorrhage, the greater number of which prove to be due to abortions; in fact, 550 cases of abortion were admitted during the period covered by the three cases described. The occurrence of cases such as these points to the urgent need for a full blood examination in all cases of uterine haemorrhage, before the almost inevitable dilatation and curettage operation is performed, particularly when the patient is exsanguinated or when there is any haemorrhage into the skin or from any other unexpected site. In such cases the operation cannot be expected to be of any benefit to the patient, but would only be an additional and major discomfort in the course of a most distressing illness.

Reviews

THE BEGINNING OF LIFE

The Physical Basis of Life. By J. D. Bernal, F.R.S. (Pp. 80. 6s.) London: Routledge and Kegan Paul. 1951.

When Wöhler in 1828 showed that urea can be made from laboratory chemicals he broke down one of the high walls between the worlds of living and dead matter. More recently the discovery that some viruses can lie dormant as crystals for years, and then come to life on their host, seemed to break down another wall. But no such wall is ever the last; and to this day no scientist can sustain with experiments his private conviction that the organic molecules have grown from the inorganic molecules by natural and intelligible steps.

Professor Bernal is not a man to shirk his convictions, and in this small but fundamental book he has not been content with any makeshift answers. In what conditions could large protein-like molecules have grown? he asks. How did they reach the asymmetry which characterizes living molecules? And what was it about their structure which made them capable of copying themselves in the living process? Finally, why do the early conditions no longer hold to produce new life spontaneously to-day?

Professor Bernal answers by tracing the probable history of the sea and the air when first the earth cooled. The sea water would first contain ammonia, carbon dioxide, and hydrogen sulphide; the air would contain no oxygen, and therefore no curtain against the most penetrating ultra-violet light. Under its action, it is reasonable to think that some simple amino-acids would then be formed.

But now comes the crucial question: How would these be concentrated and built up into the first protein-like molecules? The essential property which Professor Bernal uses for this step is the catalytic action of clay in shaping molecules which grow in contact with it. This is commercial practice in the oil industry to-day, but it has not been proposed before as the foundation of a scientific theory of life. Clay alone would not grow asymmetric molecules; but quartz would; and in either case the resulting primitive protein might well have a structure stable enough to shape and copy other molecules by catalysis—that is, to become a primitive enzyme.

As for repeating the experiment, Nature can no longer do so, because plants have since filled the air with shielding oxygen. Moreover, the very growth of life has of course destroyed the aseptic conditions in which life began. It remains for Professor Bernal to improve on Nature and repeat the experiments in the laboratory.

This will not be the last book written on this subject. But it is a book of wide and vigorous learning which never compromises with its own uncertainties. Neither Professor Bernal nor the reader is meant to suppose that he has indeed hit precisely upon the very process, step by step, which Nature used to make life. But he has, I hope, killed once for all those idle speculations which look for life in the chance encounter of atoms and then learnedly compute the odds against it. Life was not created by accident; it grew continuously from its own probabilities; and Professor Bernal has made it plain that they are inherent in its simplest atoms.

J. BRONOWSKI.

BLEULER ON SCHIZOPHRENIA

Dementia Praecox or the Group of Schizophrenias. By E. Bleuler. Translated by Joseph Zinkin, M.D. Foreword by Nolan D. C. Lewis, M.D. Monograph Series on Schizophrenia No. 1. (Pp. 548. £3 3s.) London: Methuen and Co. 1951.

It would be an interesting exercise to consider what the effects on Anglo-Saxon psychiatry might have been had this classical monograph been translated from the German shortly after its first appearance in 1911. Certain it is that much of the confusion and controversy over the concept of schizophrenia—the name dates from Bleuler's book—would never have arisen if British and American psychiatrists had had earlier access to this clear exposition. It is true that excerpts have been incorporated in our popular English textbooks, so that the salient features of Bleuler's conception are familiar to all. But for many readers this translation will give the first opportunity to observe how a searching and creative mind took a mass of carefully collected clinical observations and out of these welded a comprehensive theory of the disease which has largely stood the test of time. The achievement is all the more remarkable when we recall that it took place in an era when Continental psychiatrists had not emerged from the necessary but comparatively limited "classificatory" phase.

Bleuler's restricted and cautious application of Freudian psychology to the major psychoses, his unorthodox and courageous approach to practical problems of treatment, and his penetrating and independent power of observation have made him one of the most influential personalities in twentieth-century psychiatry. All these facets of the true scientist are to be seen in this book, and here for the first time he distinguishes between primary and secondary psychological symptoms—that is, between those specific symptoms caused by the basic disease process and those accretions which are the reaction of the mind to the primary changes. Although Bleuler's application of this principle to schizophrenia has dated—as naturally many other of his ideas have dated with the passage of time—the principle itself has found wide recognition and from it has grown the "pluridimensional approach" (of Kretschmer and Birnbaum) to psychiatric symptomatology and diagnosis. Bleuler's concept of a hierarchy of symptoms—specific, constitutional, reactive, accidental, etc.—has proved far superior to the uniform sequence of "reaction types" which was conceived about the same time by Adolph Meyer. Dr. Zinkin has made a faithful rendering of Bleuler's thought and couched it in easily readable English.

W. MAYER-GROSS.

COELIAC DISEASE

Management of Celiac Disease. By Sidney Valentine Haas, M.D., and Merrill Patterson Haas, M.D. (Pp. 188; 12 illustrations. £2.) Philadelphia and London: J.B. Lippincott Company. 1951.

It is a misfortune that this book should have appeared just at a time when, thanks to the work of Dicke and others in Holland and Sheldon in London, the exact part played in this malady by carbohydrates is becoming clearer. The distinction which can now be made between the effects of wheat flour and those of wheat starch must surely lead to some modification of the Haas hypothesis, which condemns all polysaccharides. This hypothesis pervades the whole book and detracts

inevitably from its value, but students of the subject will be grateful for the history of coeliac disease, for the full discussion of clinical symptoms, and for a most useful bibliography. (It is again a minor piece of bad luck that in quoting a small contribution to the subject by the reviewer the authors have spelt his name wrongly and repeated this error in the bibliography.)

Experience gained over many years of treating hundreds of patients gives the authors much to discuss, but it has perhaps also blinded them to the value of the work of others. Coeliac disease to-day can be cured without the bananas which Professor Haas pioneered. Few would accept (pp. 123-4) that, "if cystic fibrosis of the pancreas is treated by the same dietary regimen that is used in celiac disease, the diarrhea will cease, nutrition will become normal, and if the pulmonary infiltration has not become too severe, it too will clear up." After this it is not surprising to find that the authors make light of the diagnostic value of estimating the trypsin in duodenal juice. The authors' final summarized hypothesis reads as follows: "The diarrhea of celiac disease is caused by an anthroquinone irritant produced by a micro-organism from a polysaccharide substrate." Various paths of investigation to test this hypothesis are outlined.

ALAN MONCRIEFF.

U.S. PUBLIC HEALTH SERVICES

Medical Care of Seamen. The Origin of Public Medical Service in the United States. By Robert Straus. With preface by Leonard A. Scheele, Surgeon General, Public Health Service. (Pp. 166. £1 4s.) Merchant Seaman Studies, Volume 1. New Haven: Yale University Press. London: Geoffrey Cumberlege (Oxford University Press). 1950.

The title of this book is misleadingly restricted, for the author defines the conditions under which the U.S. Federal Government has entered the field of medical services, and he traces certain trends which in his view indicate the future development of a general medical service. He shows how the Federal services have evolved through expansion and amalgamation of schemes started to meet new needs. The process is illustrated by the history of the Public Health Service, which has grown out of the Marine Hospital Service, founded in 1798 on a contributory basis.

American merchant seamen appear to have been less socially integrated than those of other countries, who came within the framework of the general public medical provision. This factor, together with the concentration of the population on the Atlantic coast, the many inland waterways crossing state boundaries, and the boarding-house racket, created a problem peculiar to the U.S.A., and one which only the Federal Government could solve. Dr. Straus summarizes the developments made in the service and the contributions from welfare agencies, unions, and ship-owners; in tabular form he compares these with the services in other countries. He shows how in 1884 the service ceased to be contributory and how it became responsible for certain preventive measures protecting the whole nation, so that in 1912 its title was changed to the Public Health Service. Dr. Straus discusses the impetus which it received from two world wars and from the Social Security Act of 1935, and brings its history up to date with brief references to its growing responsibilities and authority. The early emphasis on preventive measures is remarkable, and quotations reveal a strong social medical approach as early as 1873.

This brief study is presented in a pleasant and clear style, but the weighty reading on which it rests is apparent in the references. The author is incorrect in stating that the Marine Hospital Service had a precedent in the United Kingdom. The mistake is due to his believing that the Chatham Chest and Greenwich Hospital made provision for merchant seamen as well as for naval ratings. He has high authority for his error, since it was apparently made in Congress in 1884. It would, however, be ungenerous to dwell on this minor point in a book which so completely fulfils its purpose and which provides English readers with much information about American public medical services, previously available to them only from scattered and obscure sources.

LUNG RESECTION FOR PULMONARY
TUBERCULOSIS

The common-sense concept of the radical treatment of pulmonary tuberculosis by removing the offending organ has been attractive for many years, and sporadic attempts to execute it have been made since towards the end of the nineteenth century. Successes were exceptional until the last few years, but to-day excision is the treatment of choice for many types of tuberculosis of the lung: perhaps it will soon be accepted—in practice, as in theory—for all cases of localized disease which will not heal on their own. The results of other longer-established methods of treatment certainly allow no complacency, for, although often highly successful in individuals, considered as a whole they are far from reassuring. Snell¹ has recently reviewed 2,472 cases with positive sputum admitted to Colindale Sanatorium from 1938 to 1950; in only 27.8% did the sputum become negative. The patients in this series were to some extent selected, and the criteria of conversion strict, but these figures are not exceptional.

Fifteen years ago resections were seldom done, because fatalities, complications, and failures were so common. The different results to-day are due, first, to the advances in knowledge of pulmonary surgery and, secondly, to the use of antibiotics, particularly streptomycin. The indications for resection remain to some extent controversial. It is accepted as sound treatment for patients in whom collapse therapy—such as thoracoplasty—has failed, or is likely to fail, because of lower-lobe disease, solid foci or tuberculomas, tuberculous bronchiectasis, or severe bronchial stenosis. It is often done for giant cavities or extensively destroyed lungs or lobes. For children or adolescents who need surgical treatment resection is usually preferable, since loss of lung tissue is well compensated, whereas thoracoplasty leads to severe deformity. Resection may be done when the diagnosis is in doubt before operation and neoplasm is suspected, and sometimes for severe haemoptysis. It can be combined with excision of an overlying

empyema if an extrapleural dissection is performed, as Sarot described.² Some surgeons, such as Bickford and his colleagues³ in Liverpool, have extended the indications to include cases of localized disease in which thoracoplasty would have been expected to succeed. For small lesions an excision will often result in less loss of function than would effective collapse treatment. Among the contraindications to resection are extensive active disease outside the area to be resected; poor function of the remaining lung tissue from any cause; active endobronchial disease at the proposed site of division of the bronchus; and infection with organisms insensitive to streptomycin. Whereas collapse operations are seldom indicated except in patients with a high general resistance and stable radiographic findings, an excision may succeed in a toxic patient, occasionally even in one desperately ill with high fever and copious sputum.

Pulmonary tuberculosis is very commonly a bilateral disease, and often more widespread than radiographs suggest. By resection only the major lesion is removed. Small areas of disease are usually left behind; these remain or become healed in the same way as does the bladder after removal of a tuberculous kidney. The extent of resection necessary is indicated by preoperative radiographs. If contralateral disease is present it should be controlled by artificial pneumothorax or have shown no signs of spread for at least 12 months. Whether pneumonectomy or lobectomy is performed will depend on the distribution of the disease, but when it is localized segmental resection is often indicated, as advocated by Chamberlain.⁴ In such cases tomography, particularly in the lateral plane, should be carried out to exclude active foci in the residual tissue, and the findings confirmed by palpation at the time of operation. Local excision or enucleation of a small focus may perhaps be the ideal treatment for a contralateral lesion or for a solitary tuberculoma, but its place is not established. As microscopic tubercles are often present in apparently normal lung adjacent to the diseased area a fairly generous margin should be left; if the intersegmental or interlobar plane is obliterated a little of the adjacent normal segment can be included with the resection.

Details of operative technique vary a little in different surgeons' hands. The patient is often put into the prone position, since it allows secretions to drain into the trachea during the operation. The extrapleural approach to the hilum may make dissection easier and is said to leave the tissues less liable to secondary infection. Reinforcement of the sutured bronchus by a pleural or muscular flap may reduce the incidence of imperfect healing. Streptomycin,

¹ *Lancet*, 1951, 2, 415.² *Thorax*, 1949, 4, 173.³ *Ibid.*, 1951, 6, 25.⁴ *J. thorac. Surg.*, 1950, 20, 843.⁵ *British Medical Journal*, 1951, 2, 839.⁶ *Thorax*, 1951, 6, 230.⁷ *Ibid.*, 1951, 6, 369.⁸ *J. thorac. Surg.*, 1950, 20, 854.

with P.A.S., effectively reduces the incidence of complications and of post-operative spread of disease, and should always be given as a cover for operation. Most surgeons advise a period of three to six months' rest in bed under sanatorium conditions after the operation; the principal reason for this is to ensure healing of the residual disease. Perhaps it will later be found that in strictly localized lesions this can be dispensed with. It is hoped and expected that one of the advantages of resection as a method of therapy is that it will markedly shorten the total period of treatment. Surgeons have not yet discovered the best way of dealing with the dead space left after resection. As there are so often small healed areas of disease in the remaining lung, its overstretching by compensatory emphysema should be avoided, since this might cause a flare-up. Sometimes, especially after pneumonectomy, foreign bodies such as plastic spheres have been left in the space,⁵ but more often it is closed by thoracoplasty. This may be combined with division or crush of the phrenic nerve and pneumoperitoneum, which is best induced before the operation. After lobectomy the thoracoplasty may be less extensive, or unnecessary, and in most cases of segmental resection the space is small and no special measures are needed to close it. Thoracoplasty is usually done two or more weeks after the resection, but recently it has been shown that it can be performed at the same time, as described by Waddington,⁶ and by Cruickshank and El Papamichael,⁷ without appreciably increasing the risk.

Serious complications of lung resection for pulmonary tuberculosis are bronchial fistula and empyema, which often occur together and may be due to tuberculous or to secondary infection. Spread or reactivation of disease is less common. No series of patients have yet been followed for very long. Bickford and his colleagues have reported on nearly 100 cases, observed for a year or longer: two of the patients died while under observation, but a positive sputum had become negative in 87% of the survivors. Day and his colleagues⁸ treated 202 patients by resection; 25 died, but of the remainder 85% had negative sputum. Similar figures have been reported by other American authors.

HOUSE DUST AS AN ALLERGEN

It is surprising that more effort is not being devoted to the study of allergy, for according to one authority "allergic diseases, with a prevalence of 1,337 per 100,000 population, are commoner than gastric, duodenal, peptic, and anastomotic ulcers combined, than all forms of anaemia, between three and four times

as common as angina and valvular heart disease combined, and rheumatoid arthritis, osteoarthritis, and spondylitis combined."¹ Unfortunately the techniques used by earlier investigators were qualitative only, and the initial enthusiasm surrounding the discovery of so striking a phenomenon led during the immediately succeeding years to much uncritical work and earned for the subject a certain degree of disrepute in this country. Despite the unpopularity of allergy as a subject of investigation, certain outstanding investigators have during the last two or three decades added greatly to our knowledge of the fundamental principles governing allergic responses. A new era seems now to be dawning in this field of research, owing largely to the application of the techniques of microchemistry and biophysics, which render possible investigations upon a quantitative basis.² The importance of the working hypothesis in the advancement of medical science still remains, as Professor J. R. Squire ably demonstrates in the paper published in the opening pages of this issue, but the validity or otherwise of hypotheses in the realm of allergy can be more readily tested when a quantitative approach can be made.

It appears evident at once that there is no satisfactory method for the standardization of the commonly occurring allergens (such as pollens, dander, or dusts), since there is no relation between potency as tested on the patient and either weight or content of total nitrogen or protein nitrogen. The present stage of development is similar to that reached in the early days of vitamin research, and the only possible recourse seems to be to an arbitrary standard preparation of the material in question, but with the added difficulty that the human subject should really be used for comparison—though multiple sensitivity is just as likely to occur in such a subject as did multiple deficiencies in the animals used for vitamin assay. There is still a great need for further purification and characterization of the known common allergens.

House dust is one of the commoner causes of specific sensitization, estimates of its incidence in asthmatics having varied between 33 and 79%.³ Assessment of the exact incidence of hypersensitization is made difficult by the possible occurrence of weak positive reactions due either to low-grade sensitivity in patients without clinical symptoms or to non-specific irritant material. By its very nature house dust might be expected to contain a great

⁸ *Ibid.*

variety of allergens, yet most investigators have been struck by the rather highly specific character of house-dust sensitivity. Rimington, Stillwell, and Maunsell,⁴ by purifying the active material, obtained a product which proved to be a polypeptide-like unit combined with a polysaccharide, or a complex of such chemically similar materials. Biological activity was shown to reside in the nitrogen-containing portion of the molecule, since controlled degradation removed the greater part of the carbohydrate without decrease in potency. Acid hydrolysis liberated several common amino-acids, but the basic and aromatic amino-acids were notably deficient. The purified allergen did not give the usual protein reactions, and it is noteworthy that solutions of it may be boiled without loss of activity. It would appear, like the blood group specific substances, to belong to a class of biochemical materials, so far little investigated, in which amino-acids and carbohydrates are associated in a large complex molecule. From three different moulds (*Caldariomyces fumago*, *Penicillium roqueforti*, and *P. tardum*) grown in pure culture the same workers⁵ obtained products similar in composition to the house-dust allergen and reacting specifically in hypersensitive persons. Further research upon these mucopolysaccharide-like materials is urgently required.

Three principal hypotheses have been put forward to explain the presence of the specific material in house dust: first, that it is derived from the air-borne spores of common moulds; secondly, that it arises from the disintegration of textile fibres, such as cotton, under physical influences (light, heat, etc.); and, thirdly, that it is formed as a result of the action of micro-organisms upon fibres or furnishing materials and is not present in either separately. A brief examination of these possibilities may be of interest. Much work has been devoted to the identification of moulds inside and outside houses and to the testing of dust-sensitive patients with mould extracts, but little support has been gained for the first hypothesis—there is in general a lack of quantitative relationship between dust and mould sensitivity. Similarly the support for the second hypothesis is but meagre. Extracts of "old" fibres often cause large reactions, but in an experiment by Wagner and Rackemann,⁶ in which new kapok was "aged" under sterile conditions, no active material was produced in six months. Subsequent spraying with moulds (themselves incapable of giving positive skin reactions) from old kapok quickly led to the formation in the kapok of typical biologically active material. Such a result supports the third hypothesis. Still further support for this possible origin of the house-dust allergen is afforded by Maunsell's⁷ investigations of the

situation of the homes (in the London area) of dust-sensitive patients with bronchial asthma or perennial rhinitis. Thirty-eight out of 49 patients lived, at the onset of their disease, in houses within 180 yards from open or underground waterways, as against 17 out of 49 strictly comparable controls. Though many of London's small waterways have for long been enclosed in concrete sewers, the clay in their neighbourhood probably has a higher humidity than elsewhere, because rain water over a large area must still gravitate to the regions occupied by these drains. Moulds probably grow more freely in houses built on such damp ground than in houses further from the watercourses. Harsh⁸ has pointed out that the warm, humid coast of California, with its low pollen and fungus counts, constitutes an ideal natural laboratory for the study of the effect of climate in allergy, especially since more than 75% of the adult population has lived previously in drier inland areas. As a result of his observation of patients with respiratory allergic diseases who are sensitive to house dust or pollen he concluded that the effect of a damp climate may not be due to external operation of the climate *per se* but rather to an effect of the humidity in potentiating the allergen.

At this stage it would be well to recall Professor Squire's analysis of the place of hypothesis in the advancement of medical science. The problem of house-dust sensitivity is difficult, and the hypotheses briefly referred to above are provocative; but it will be interesting to see how they bear up under further well-directed experimental assault.

SPECIFIC LANGUAGE DISABILITY

The occurrence of specific language disabilities in children of normal intelligence has long been recognized. Under the rubric of "developmental aphasia" a variety of clinical pictures have been described in which the main feature is "lack of facility in the various aspects of handling words: reading, spelling, talking, and writing." It is rare, however, for all uses of language to be affected equally, and severe retardation in reading or spelling (or both) without any difficulty with speech is quite common. Curiously enough, calculation is seldom affected. The incidence of such defects in the general population has been placed as high as 10%, and there is some reason to believe that they are commoner among boys than girls. The causes and treatment of specific language defects should be more intensively studied, for educational reasons as well as for their relevance to the theory of aphasia. Gallacher,¹ for instance, feels that school medical officers and others concerned with the management of retarded children should give fuller recognition to the

Reports of Societies

CRIMINAL RESPONSIBILITY

The Section of Psychiatry of the Royal Society of Medicine held a joint meeting with the Medico-Legal Society on December 11, 1951, at 1, Wimpole Street. Dr. DESMOND CURRAN, the president of the Section, was in the chair. The subject was "Different Approaches to the Problem of Criminal Responsibility."

An extremely interesting evening resulted, limited only by the time available, many of those present being still anxious to contribute to the discussion when the meeting ended at 10.30 p.m. One speaker made a very relevant observation when he said that the witness-box was not a platform from which to ventilate psychiatric theories, and from the general response it was clear that the meeting agreed with this view. The meeting did, in fact, afford a good opportunity for the presentation of the various opinions on the subject without the intrusion of the sensational element usually associated with the ordinary murder trial. Weight was undoubtedly added to the discussion by the obvious experience and authoritative opinion of the various speakers. It seemed that the general opinion was that the M'Naghten rules could not be improved upon, offering as they did a fair legal approach, at the same time the accused's interests being safeguarded by the various other sieves through which his case is passed. One speaker went so far as to declare that psychiatry was not yet in a position to give an opinion sufficiently definite to demand changes in the law. There also appeared to be a strong feeling that, as fitness to plead was not the same as insanity, the case should not be lightly taken from the jury merely because the prisoner showed mental changes.

Fitness to Plead

Sir NORWOOD EAST opened the discussion by indicating that he proposed to deal only with responsibility in cases of murder and in connexion with (1) certification without trial; (2) fitness to plead; (3) guilty but insane; (4) irresistible impulse; and (5) medical inquiry after trial. Throughout his paper he quoted freely from the evidence given before the Royal Commission on Capital Punishment, and emphasized the contrary views expressed by eminent legal and medical authorities. He said that although certification without trial could take place, this in fact rarely did occur. On the other hand, the question of fitness to plead was a common issue to be tried by a jury in England, while in Scotland the so-called plea in bar of trial was frequently decided by the judge alone. He felt that whenever possible the accused should not be deprived of his right to plead and assert his innocence and prove it if possible, and this was particularly applicable when the accused would be left with a feeling afterwards of not having had the opportunity of a full and fair trial. He did, however, feel that he should mention that four experienced prison medical officers had given evidence before the Royal Commission to the effect that they felt that a man, if certifiable as insane, should not be placed in peril by trial. But he added that this did not express the view of some other equally experienced prison medical officers. Divergent opinions on this matter were also expressed by authorities outside the prison service.

The M'Naghten Rules

The issue of insanity at the time of commission of the offence was covered by the M'Naghten rules, which had stood the test of time and defined not insanity according to medical tests but the legal concept of the responsibility of a person for his action. The rules were probably more liberally interpreted nowadays and for that reason had kept

up to date with any change in views. At the same time, it was of interest that the British Medical Association, in evidence before the Royal Commission, had agreed with the rules but had suggested that irresistible impulse should be grounds for acquittal. The difficulty, however, was to establish when an impulse is irresistible and when not resisted. In his experience a true irresistible impulse had not been the cause of murder except in association with mental disease, and had then been accepted as ground for acquittal.

The Home Secretary's Powers

Sir Norwood went on to discuss the medical examination which the Home Secretary might order to be carried out by two or three doctors after a person had been convicted of murder, for the purpose of establishing whether he was, or was not, sane at the time of the examination as in contradistinction to the time of the offence. He here quoted an eminent legal authority as having said that it did not seem proper for doctors to express an opinion on a matter which had already been decided by a jury when insanity had been put forward as a defence at the trial, except in very special cases. He himself thought that the method was just and merciful, and would take into consideration any question of mental deficiency. He also mentioned that evidence during such an inquiry was always taken from the prison chaplain and that he had been most impressed by the agreement of the chaplains with the eventual findings.

The Jury

Mr. ANTHONY HAWKE spoke on the legal aspects. He said that the whole basis of the matter was "Justice shall be done" and "Injustice shall not be done." He felt that he had nothing new to add but would like again to stress that the question of criminal responsibility should be left to be decided by the good sense of the fellow men and women of the accused, properly directed and assisted by the lawyers and doctors. If the jury was to be the right tribunal then it was essential to remember what the issue really was—namely, not "Is this man insane?" but "Is he to be held responsible for the act that he has committed?" If this was right, then there must be some sensible and intelligible limits within which criminal responsibility could be measured, and the M'Naghten rules satisfied this as well as anything. He pointed out that the legal principles on which the rules were based had existed long before 1843. He said that the rules had two limbs, the first of which seemed to present no great difficulty—namely, "whether the person understands the nature and quality of the act." The second limb, however—"Did not appreciate at the time that what he was doing was wrong"—was much more difficult. He thought that the second limb would cover the question of irresistible impulse, for if the person thought that what he did was the only possible thing to do, and so must be done, then if this feeling was prompted by a defect of the mind, substantiated by medical evidence, it must come within the second limb. If, on the other hand, it was not prompted by such a defect of reason, then it would seem that the impulse could have been resisted.

Refusal to Plead Insanity

He was strongly in favour of the medical inquiry after conviction in proper cases, and said that he could not agree with the authority who had said that holding such an inquiry after conviction was liable to result in a conflict with the findings of the jury, because what the jury had decided was not that the person was sane but that he had been responsible for the act that he had done. Perhaps it was not realized that unless the accused instructed his counsel to do so a plea of insanity could not be raised, and he himself had had experience of more than one case in which the accused was, in fact, insane (and was so found by the doctors after conviction), but would not allow such a defence to be put forward at the trial.

On the question of the issue of fitness to plead he entirely agreed with Sir Norwood East that a person should not, save in exceptional cases, be deprived of the right to establish his innocence, or for that matter to demand that the prosecution should prove his guilt.

Discussion

Professor E. W. ANDERSON agreed with Sir Norwood East in doubting the so-called irresistibility of impulses. He further said that the extravagance of some of the exponents of this thesis had led psychiatry into disrepute. Finally, after describing an extremely interesting case he had been able to investigate of a well-to-do young man resident in a mental hospital instead of prison, he said that, although he felt that punishment should fit the criminal and not the crime, that end was not always attained by such measures.

Dr. J. C. MCL. MATHESON had seen only one case of certification before trial, but he could envisage a person whose mental condition was so serious that he required urgent and immediate treatment. He mentioned that once a person had pleaded guilty to an offence he could be certified only from the prison and not in court. He himself was sometimes surprised by the ease with which the court accepted evidence of unfitness to plead, especially as it involved the risk of an innocent person being detained without trial. He quoted the case of a man with general paralysis of the insane who, although medically certifiable, had contested the charge against him and had been acquitted upon the evidence. Finally, he referred to the electroencephalograph, and pointed out that it could never resolve the question of responsibility.

Dr. T. C. N. GIBBENS, who had studied the problem in the United States of America, said that most States employed a variation of the M'Naghten rules, but there were one or two interesting deviations. In one State there were no tests and the matter of responsibility was treated as fact and decided by the jury, while in another there were two separate trials by jury—one on responsibility and the other on guilt. He suggested that the verdict of "Guilty but insane" was illogical; in America, if you were found insane, you were not guilty. The question of diminished responsibility was covered by the various degrees of murder. He thought the modern interpretation of the M'Naghten rules was broad. The law in respect of provocation was far from being in tune with modern psychiatric views, but no lawyer thought it could be amended.

Dr. J. A. HOBSON said that if it was true, as suggested by the opening speakers, that justice was always done, it was not because of the M'Naghten rules but because of the common sense with which the Courts misapplied them. Though he was prepared to believe that insane murderers did not hang, he also believed that justice was not always done in the opposite direction. There seemed no doubt that many sane murderers became Broadmoor patients.

The Minister of Health has approved the appointment of Mr. B. O'Brien to be solicitor and legal adviser to the Ministry of Health in succession to Sir Thomas Harrison, who has retired from the Civil Service. Mr. O'Brien will also act as solicitor and legal adviser to the Ministry of Housing and Local Government. Mr. O'Brien joined the Ministry of Munitions in the first world war and transferred to the Treasury Solicitor's Office in 1920. He became a member of the legal staff of the Ministry of Health in 1929, and has been closely concerned with legislation connected with many aspects of the work of the old Ministry of Health. During the last war he was seconded to the Ministry of Food, where as an assistant secretary he was in charge of supplies of food to hotels, restaurants, and other catering establishments as well as to hospitals, schools, and institutions. Sir Thomas Harrison entered the Ministry of Transport after military service in the first world war, and became an assistant solicitor to the Ministry of Health in 1929. He was appointed solicitor and legal adviser in 1934.

Preparations and Appliances

A ROTATABLE SHEATH RESECTOSCOPE

MR. J. E. SEMPLE, F.R.C.S., surgeon, St. Paul's Hospital for Genito-Urinary Diseases, London, writes: The importance of being able to resect the anterior part of the prostate gland as easily as the posterior, while manipulating the resectoscope with one hand, has given rise to a demand for an instrument in which the sheath and cutting loop can be freely rotated through a full circle without moving the position of the operating hand. It seemed that this could be most easily accomplished if the metal cone on to which the bakelite sheath is locked could be extended backwards in the form of a metal tube, which would rotate freely within the framework of the instrument and down which the telescope could be inserted. On this metal tube a bobbin of bakelite would slide freely up and down, but rotating with the tube, to which it would be keyed; into this bobbin would be fixed the proximal end of the loop electrode and through it connexion with the diathermy machine would be made.

The main feature of the instrument here illustrated is its extreme simplicity in design and construction. The telescope is of the wide-field, fore-oblique, McCarthy type, which gives an excellent view without loss of definition. In this resectoscope the telescope remains stationary throughout the cut, but if preferred it can be made to withdraw at the end of the cut by the usual mechanism, which is an optional fitting. The cutting loop is controlled by a scissors type of grip, by which the bobbin holding the proximal end of the electrode is advanced or withdrawn by the index and middle fingers while the thumb controls the framework of the instrument. The loop can be made to return automatically to the forward position, after the cut has been finished, by a spring incorporated in the framework, if such is desired, but the control seems more delicate if finger pressure alone operates the loop. The bakelite sheaths are supplied in two sizes for each instrument, F 26 and F 28, so that a urethra of small calibre need not be unduly injured to admit the sheath, yet the advantages of a large-loop electrode are not forfeited. The sheath is attached to the rotating spindle by a ready release-and-lock cone, which makes removal of the telescope and electrode especially easy. The irrigating system is a fixed part of the framework, and is controlled by a wide-bore two-way irrigating tap. The whole instrument can be made boilable.

This resectoscope has been proved to cut very well in all positions and is very pleasant to operate, making the preliminary dissection of the anterior segment of the prostate much easier and therefore more complete.

I have to thank Mr. Lowery and the staff of the Endoscopic Instrument Co., 62, Shirland Road, London, W.9, for their help in constructing this resectoscope.

Your recipe for winter well-being?

Usters and umbrellas? Menthol and mustard baths? Yes, but these can never be more than the decoration and the seasoning. The main ingredient must be sound nutrition—a sufficiency of the protective and formative vitamins A and D in particular.

That is why the name **ADEXOLIN** heads the winter $\mathcal{R}$ list for so many patients, or **ADEXOCAL** if extra calcium is needed to stave off chilblains.

ADEXOLIN Capsules

Trade mark

Mainly for adult patients
6,000 units vitamin A and
1,000 units vitamin D per capsule
Tins of 25 and 100

ADEXOLIN Liquid

Trade mark

Especially suitable for infants
12,000 units vitamin A and
2,000 units vitamin D per cc.
Bottles of 14 cc. and 2 oz.

ADEXOCAL Tablets

Trade mark

Extra protection against chilblains
6,000 units vitamin A
1,000 units vitamin D and
300 mg. calcium phosphate per tablet
Bottles of 50

Death on the Roads

SIR,—I read with interest the report in the *Journal* of December 8, 1951 (p. 1399), of the discussion on "Alcohol and Road Accidents" at the Pedestrians' Association's Conference, November 24, 1951. I agree with many of the points made by various speakers, but it would appear that some statements were made which are ill-founded and may be quite misleading. For example, although it is true that many accidents occur between 10 and 11 p.m. it is not necessarily true that this is due to the advent on the roads at this hour of an increased number of drunken motorists. Perhaps there are more drunken motorists about; perhaps it is simply that there are more motorists about. It may be that there are more drunken pedestrians on the road; or simply that there are more pedestrians. It is very unsafe to come to a definite conclusion that any one factor is responsible for the 10 to 11 p.m. peak.

Indeed, a graph which I prepared some years ago (*Practitioner*, 1945, 154, 205) showed that there were four peak periods. On week-days the highest peak was between 5 and 6 p.m.; the second highest between 12 noon and 1 p.m.; the third highest between 7 and 8 a.m., and the fourth highest between 10 and 11 p.m. On Saturdays the highest peak was between 12 noon and 1 p.m., and the second highest between 10 and 11 p.m. It is most improbable that the 12 to 1 p.m. peak has anything to do with alcohol consumption, and it is most unwise to assume that the 10 to 11 p.m. peak is necessarily related, solely or even mainly or at all, to the fact that the public houses close about 10 p.m. Cinemas, theatres, and concert halls also disgorge their clients about this time, and it is not only the drunken motorist who is bustling to get home.

The figures on which my references are based were those of the Ministry of Transport Report on *Road Accidents in Great Britain involving Personal Injury for 1936-7*. Now that the five-day working week is fairly widely operative, it may be that more recent figures would show an alteration in the Saturday peak periods.

A further interesting point which emerged from my analysis of the 1936-7 figures was that, whereas there were altogether nearly 173,000 accidents involving car drivers, cyclists, and pedestrians, only 0.8% were definitely attributable to the effect of alcohol in either the driver or the pedestrian, and only 0.3% in which the driver was definitely under the influence of alcohol. A further remarkable fact was that of all the fatal accidents during that period (5,645), there were only 25 in which the car driver was clearly under the influence of alcohol. Of course, as Dr. Goodhart stated, these figures of proved drunken drivers take no account of the large numbers of drivers whose sense of responsibility has been weakened by doses of alcohol which might not be clinically discernible. There is no doubt whatever that an amount of alcohol which is insufficient to cause clinical symptoms, and might be looked upon as not particularly important, can in certain cases produce an effect on the control of the individual.

It seems to me that medical tests in "sub-clinical" cases are of little value. If it is felt that the case against alcohol is sufficiently established, the only course open would appear to be to insist on a blood examination in all cases and to regard the finding of any alcohol at all in the blood as being sufficient to warrant prosecution and conviction. This obviously would mark a serious departure from the present conception of crime and of the rights of the individual, but it would seem to be the only logical way of approaching the problem legally. Motorists would then know that they dare not drink at all if they are in charge of a car, and if

they must go out to dinner they must make arrangements for their return home by taxi or otherwise. Whether this proposal is advisable is an entirely different matter.—I am, etc.,

Edinburgh.

SYDNEY SMITH.

SIR,—I read with interest the report in the *Journal* of December 8 (p. 1399) of the discussion at the Pedestrians' Association's Conference of November 24, 1951. I have been concerned in the large number of cases of "Drunk in Charge" both at the Metropolitan Police Laboratory and more particularly at the North-eastern Forensic Science Laboratory, and as a result of this experience there are one or two points on which I should like to comment.

First, Dr. A. L. Goodhart, K.C., says that it is not the drunken driver who was the main concern of the meeting. I regret that my experience does not bear this out. Ultimately, I have no doubt this statement may be true, as it is now true in the Scandinavian countries. Unfortunately, in this country we have not yet succeeded in dealing satisfactorily with the drunken driver. In the *Medico-Legal Journal* (1951, 19, 98) I and my colleagues published a graph of our results on the examination of somewhat over 600 cases, which peaks strongly at 0.30% alcohol in the urine. This means that the drivers had consumed not less than 6 pints (3.4 litres) of a strong beer, such as draught Bass, or nearly half a bottle of spirits. This can scarcely be regarded as a moderate consumption, and this peak of 0.30% is considerably higher than Andresen's peak of about 0.22%.

Secondly, Captain A. Popkess refers to the variation of accident rate with the time of day. Our information is in strong agreement with Captain Popkess's suggestion. The following is a tabulation of the time of arrest of the last 543 cases examined in the counties of Durham and Yorkshire between May 1, 1949, and December 18, 1951. This Table shows that the percentage of the total arrests which occurred during the hours 10 p.m. to 12 p.m. is extraordinarily large. There is also a small hump which would appear to coincide with the afternoon closing hours.

Time	Number
Before noon	4
12 noon to 2 p.m.	1
2 p.m. to 4 p.m.	28
4 p.m. to 6 p.m.	34
6 p.m. to 8 p.m.	29
8 p.m. to 10 p.m.	74
10 p.m. to 12 midnight	263
12 midnight to 2 a.m.	92
2 a.m. to 4 a.m.	16
4 a.m. to 6 a.m.	2

543

New Scotland Yard, S.W.

L. C. NICKOLLS,
Director, Metropolitan Police Laboratory.

SIR,—For many years I was a police surgeon and I have read with great interest the correspondence following the report (December 8, p. 1399) of the discussion on this subject. I fully agree that any reliable test of the alcohol content of either blood or urine would not only act as a deterrent to the dangerous driver who may drive too soon after a party but definitely help to distinguish the real alcoholic, probably sobered by the accident before examination by the police surgeon, from the nervous hysteric whom the fright of an accident may render incoherent.

Whilst, however, not intending to minimize the danger of the loss of fine control and quick reaction after very slight doses of alcohol, I would like to draw attention to the obvious unfairness of any legislation so extreme as is suggested, such as the prohibition of driving within two hours of even one small drink. So many other conditions are, in my experience, at least equally conducive to loss of efficiency in drivers—namely, fatigue, hunger, lack of sleep. It was a matter of regular experience on pre-war Sundays, when road accidents occurred every week, that most

happened between 12.30 and 1.30 p.m. or between 5 p.m. and 6 p.m. I think that hypoglycaemia must be a factor in the "accident prone." It will be most helpful to drivers and to doctors if some observations could be made and published on the complete physiology of the drivers in accidents.

It is pertinent to remind your readers that the question of alcoholism cannot have influenced my observations on the times of accidents, as there are no licensing hours in Wales on Sundays, and we live twenty miles from the border.—I am, etc.,

Ruthin.

TREVOR HUGHES.

Fantus Estimation of Urinary Chloride

SIR,—It is still widely believed that the urinary chloride level usually reflects the serum chloride level, and the Fantus test is commonly employed as a guide to electrolyte therapy, especially in surgical practice. Dr. W. H. Taylor has performed a valuable service in drawing attention to the fallacies of the test (November 10, p. 1125). As he points out, however, even more accurate methods of determining the urinary chloride concentration are not necessarily a reliable guide to serum levels. We are particularly interested in those cases, mainly post-operative, in which the urinary chloride concentration is normal or high and yet the serum chloride is low. Following major abdominal operations in children, particularly when there is loss of gastric or intestinal secretions by continuous aspiration, fistulae, or diarrhoea, these findings are not uncommon and are often associated with potassium depletion. Dr. D. A. K. Black (November 17, p. 1207) has described the clinical manifestations of potassium deficiency and the circumstances in which it is liable to occur. In the surgical cases there is excessive potassium loss in the urine as well as in the gastric and intestinal secretions. Potassium is excreted in the urine mainly as chloride, thus leading to a fall in the serum chloride level. Attempts to correct the chloride deficit by enthusiastic infusion of sodium chloride lead to an increasing loss of potassium, mainly in the urine, and a dangerous state of potassium depletion may arise. Diuresis may also occur following such infusions even though the clinical state of dehydration is not fully corrected and may, in fact, even become worse. At this stage the condition may be incorrectly interpreted as being due to sodium deficiency only, and even more sodium chloride may be given, with possibly fatal consequences. As Dr. Black points out, the clinical picture of potassium deficiency may be difficult to assess, but valuable assistance can be obtained from the electrocardiogram, estimations of the serum and red cell potassium, and of the urinary potassium excretion.

The point we wish to emphasize is that potassium deficiency in this type of case is common, at any rate in children, and is often unrecognized. The combination of low serum chloride and high urinary chloride levels should suggest the possibility of potassium deficiency and should call for fuller investigation in order that adequate electrolyte therapy can be given. If these investigations are not practicable potassium therapy, either parenterally in the form of Darrow's solution, or orally, should be carefully considered in all such cases. Although Darrow's solution can be given safely intravenously so long as the rate is not too rapid and renal function is satisfactory, we have found that it may not be sufficient to correct the potassium deficiency and may have to be supplemented by oral therapy.—We are, etc.,

Hip Reconstruction by Acrylic Prosthesis

SIR,—Many surgeons will have welcomed the letter of Mr. W. Gissane (December 8, 1951, p. 1401), and the warning which he sounded against premature adoption of the method of femoral head replacement for subcapital fractures of the femoral neck. He still favours insertion of the tri-

flanged nail under radiographic control, and expects that this will achieve from 50–60% of successes. Only when this has failed would he resort to the acrylic replacement operation. Dr. R. Judet, who, with his brother and other French surgeons, has developed the use of the acrylic prosthesis, is also emphatically against the general abandonment of the nailing operation in favour of this new method.

The nailing operation, under radiographic control, has always occupied a peculiar position in surgery. If we accept Mr. Gissane's figure of 60% successes, there can be few procedures, outside cancer surgery, where an operation with such modest claims has held its place as the standard procedure for many years. It is an operation of precision and in successful cases gives a perfect result. If unsuccessful, failure is usually complete. It may be said that the nailing operation has remained the standard one because of its very low rate of mortality, even in the very aged, and because there has been no real alternative operation of wide application. Although there have been innumerable contributions to surgical literature on this subject, most of them have been concerned with modifications of technique and new devices for avoiding the causes of failure. Few papers have appeared which have given the long-term results of the nailing operation. Such series as have been reported have, in the main, shown very disappointing results. It is not surprising, therefore, that there should be a ready welcome for what purports to be a promising alternative to an operation which has to admit to a 40% rate of failure.

The most important thing, as Mr. Gissane points out, is that this new operation should be given its trial under the most favourable conditions. That means good selection of cases, a high standard of operative technique, and careful post-operative management in the initial stages. In this latter respect there is a marked contrast to the nailing operation, in which the chief problem of after-treatment has centred on the resumption of weight-bearing.

The results of the nailing operation, in my opinion, have never been adequately reported, and even now it would help to clarify the situation if more results were published. It is greatly to be hoped that a better method may be found for the assessment of the results of the acrylic replacement operation. It should not be difficult for one of the surgical associations to set up a bureau or register to collect data of a large number of subcapital fractures treated by the acrylic method, and their progress at regular intervals. Only by the fullest clinical reporting can an early valuation be made of this new method, which may have such far-reaching possibilities.—I am, etc.,

Guildford.

G. N. GOLDEN.

Pre- and Post-operative Treatment of Dehydration

SIR,—Dr. W. H. Taylor's criticism of urinary chloride estimation (November 10, p. 1125) must have been welcomed by many who see it being used as the sole guide to intravenous therapy, especially in the post-operative period. Dr. H. L. Marriott's letter (November 24, p. 1284) must, however, be accepted as a well-balanced survey of the value of urinary estimations in the treatment of dehydration compared with plasma concentrations. He did not, I feel, emphasize sufficiently the fact that in this post-operative or post-traumatic period the widespread faith in Fantus's test can be entirely misleading.

Dr. Marriott suggests that the post-operative retention of sodium is due to a renal attempt to bolster the diminished plasma volume; he therefore suggests plasma or saline as a replacement fluid. Saline, however, will be split between the vascular and interstitial compartments, while plasma or plasma substitute will be retained in the vascular compartment. Surely, if any intravenous fluid is to be given during an operation or after other trauma to bolster plasma volume, plasma is always indicated. In view of the many suggested causes of post-operative retention of sodium (Darrow and Pratt, 1950) and the suggestion by many of the importance of an adrenocortical mechanism (Selye, 1949; Wilkinson *et al.*, 1951; Finley *et al.*, 1951) there is further cause for not administering saline in these patients. Finley *et al.* have also shown that there is still sodium retention in patients who have plasma volume maintained by infusions of plasma substitute.

Suggested Scheme of Treatment.—First, we must insist upon the correction of a serious pre-operative defect. To myself, as an

*For Safe and acceptable
Sulphonamide Therapy!*

'Cremotresamide' reduces the incidence of crystalluria — the primary factor causing renal complications in patients undergoing sulphonamide therapy.

'Cremotresamide' produces and maintains highly effective blood levels.

'Cremotresamide' combines low toxicity, excellent tissue distribution and good therapeutic efficiency.

'Cremotresamide' is particularly acceptable to children, but will be found useful in all age groups.

Descriptive literature, clinical package and practical dosage card gladly forwarded on request.

Sharp & Dohme Ltd., Hoddesdon, Herts.

'Cremotresamide'

Triple Sulphonamide Suspension

YOU'D HARDLY CALL THEM MILKSOPS BUT—

How would YOU maintain a high-protein diet?

WHEN YOU PRESCRIBE a high-protein diet today it is worth remembering that a casein product such as Sanatogen will provide your patient with all the nutritive protein of meat—with none of the rationing difficulties. The protein value of a normal daily dose of Sanatogen is equal to the amount in 6 oz. of lean beef. The use of Sanatogen is one of the best and most practical ways today of ensuring a high-protein diet in such conditions as malnutrition, convalescence, certain types of nephritis and hepatitis, toxæmia of pregnancy, sprue, coeliac disease and colitis, after severe burns or other injuries, and also during the dietary treatment of obesity. Extra protein needed in pregnancy and lactation can be supplied by Sanatogen and it is excellent in diabetes mellitus as it contains no carbohydrate.

95% PROTEIN—NO CARBOHYDRATE

Sanatogen contains 95% casein with the addition of 5% sodium glycerophosphate. The purity and quality of its protein content are unsurpassed. Containing neither fats nor carbohydrates, Sanatogen is absorbed almost twice as quickly as casein dissolved by sodium, as shown by physiological and clinical experiments.

INDICATIONS. Sanatogen can be recommended when a high-protein diet is prescribed, especially if the absorptive powers of the digestion are feeble, and is an invaluable supplement to the ordinary diet. Practitioners who wish to carry out their own clinical tests will be given every help. Please write to the Medical Department, Genatosan Ltd., Loughborough, Leicestershire.

SANATOGEN
FOR HIGH-PROTEIN DIETS

The word 'Sanatogen' is the registered trade mark of Genatosan, Ltd., Loughborough, Leics.

Obituary

A. GARRICK WILSON, M.Chir., F.R.C.S.

Mr. A. Garrick Wilson, senior consulting surgeon to the Royal Hospital, Sheffield, died on December 10, aged 76.

Of Scottish descent, the son of a well-known medical officer of health, Wilson was early imbued with a deep sense of medical responsibility. From Cambridge he went on to St. Mary's Hospital with a university scholarship, and he graduated M.B., B.Ch. in 1899. Deciding to specialize in surgery, he took the F.R.C.S. in 1901 and the M.Ch. four years later. After holding resident posts at St. Mary's he became surgical registrar there. His appointment as senior house-surgeon at the Sheffield Royal Infirmary was followed later by his election to the visiting surgical staff of the Royal Hospital. In the course of the many years that he served this hospital he became widely recognized for the soundness of his work and the thoroughness with which he carried out everything to which he put his hand. No detail was too trivial for his attention if it might possibly contribute towards the welfare of any patient. He had the reputation of a skilful, safe, and tireless operator, but these qualities were dwarfed when laid beside his outstanding attention to the minutiae which so often made the difference between failure and success. In collaboration with his colleagues on the physicians' side he was at his best—courteous, attentive, ready to state a firm opinion, but more than willing to accept a contrary viewpoint when reasonably probable. In carrying out the necessary surgical procedure resulting from a consultation he was loyalty itself. Highly sensitive to any form of injustice or arbitrary use of power, he became sometimes involved in disputes with those whom he considered lacking in full sense of responsibility, and in such respects his annoyance was not easily allayed. But it was generally recognized by his colleagues that any outburst sprang from essentially noble impulses and were untinged by personal envy.

Wilson held many appointments in and near Sheffield. He was lecturer in clinical surgery at the university, orthopaedic surgeon to the Chesterfield Royal Hospital, consulting surgeon to the King Edward VII Hospital for Surgical Tuberculosis, president of the Sheffield Medico-Chirurgical Society, and chairman of the Sheffield Division of the B.M.A. (1924–5). During the first world war he served in the R.A.M.C. as a major.

Among residents, students, and the humbler members of the hospital surgical service Wilson was noted for the care with which he guarded their interests; he went out of his way to investigate their welfare. In his family and among his more intimate friends he was deeply beloved and respected. Suffering much both in personal ill-health and in bereavement, he bore all with cheerful equanimity. His premature resignation from the staff on account of ill-health left a blank that was deeply felt. In his retirement he was a happy man, enjoying his garden in Beaminster, Dorset, and the simple domestic duties of a country life.—A. E. N.

The death of Dr. N. MOOTATAMBY on November 8 came as a shock to his family and to his numerous friends throughout Malaya. He was born in Ceylon in 1892, but went out to Malaya at an early age. He qualified from the College of Medicine, Singapore, in 1917, and except for the following

three years, which he spent in the Johore Medical Service, he was a private practitioner in Johore Bahru for the rest of his life. He was an enthusiastic member of the British Medical Association and took a keen interest in all its activities, being chairman of the Southern Division of the Malaya Branch in 1950–1. He was a true Malayan at heart and gave freely of his services to the country of his adoption, being on numerous committees and boards besides having served three periods of three years each on the State Council of Johore. His services to the Johore State were recognized by the Sultan when he was awarded the Dato Paduka Makota Johore in 1950. In addition to this he was an ideal medical practitioner and a very lovable person, as all his friends know. There must be numerous old Malaysians in the United Kingdom who will remember him and regret his death.—C. H. C.

Dr. LUDOLPH BRAUER, emeritus professor of medicine at Hamburg, died on November 25, aged 86. He was educated at Bonn, Marburg, Munich, and Freiberg, and qualified at Heidelberg in 1897. In 1905 he was appointed director of the medical clinic at Marburg. Five years later he became director of the Hamburg-Eppendorf Hospital, a position which he held for many years. In 1919 he was appointed to the chair of medicine at Hamburg, and he also served as rector of the university for some years. Brauer's principal work was in the field of tuberculosis. He was founder and director of the Deutsche Forschungsanstalt für Tuberkulose, and his name is perpetuated in *Brauer's Beiträge zur Klinik der Tuberkulose*, of which he was an editor. He was also joint editor of the *Zentralblatt für die gesamte Tuberkuloseforschung* and of the *Handbuch der Tuberkulose* (Leipzig, 1914–22). He advocated collapse therapy by extrapleural thoracoplasty, and induced artificial pneumothorax by the injection of nitrogen ("Brauer's method"). The treatment of chronic adhesive mediastino-pericarditis by cardiolysis, a procedure now known as "Brauer's operation," was first suggested by him in 1903. Besides receiving honorary doctorates at Bonn, Cordoba, and Shanghai, Brauer was honorary professor of the University of Istanbul and a corresponding member of 51 scientific societies in Germany and elsewhere.

Dr. L. R. J. RINKEL, medical superintendent of the British Legion Sanatorium, Nayland, died on November 10, aged 43. Lambert Ronald Joslin Rinkel was educated at Blundells School, Clare College, Cambridge, and St. Thomas's Hospital. While he was at school it soon became apparent that he would become an athlete of the first rank, and he was in Blundells sports eight. At Cambridge he secured his Blue for the 100-yards in 1929, and he won this event at the Oxford and Cambridge Sports at the White City in 1930. He qualified in 1933, and was appointed to a resident post at St. Thomas's Hospital. At this time he became seriously ill with tuberculosis, and after his recovery he specialized in diseases of the lungs, holding appointments at the Royal National Hospital, Ventnor, and the Kelling Sanatorium, Holt. In 1946 he was appointed medical superintendent to the British Legion Sanatorium at Nayland.

S. A. P. writes: Ronnie Rinkel will be sadly missed by his many friends: he had accomplished much in his short span. I first knew him at Cambridge, where he won renown as a sprinter. He was a gay and amusing companion as a student, and a conscientious worker. In those early days the strong character which was to stand him in good stead in later trials was already evident. At St. Thomas's Hospital, where he found quite a number of his old Cambridge friends, he quickly made many new ones and took a full and active part in the hospital's corporate life. After qualification he was appointed to one of the coveted resident posts, and was a most popular member of "College House." It was during this, his first job, that he developed pulmonary tuberculosis. Gloom descended on College House when the desperate situation was understood; his past athletic career added starkness to the event. But he

faced what seemed hopeless odds most courageously—one operation followed another, but for long we had no good news. Contrary to expectations, he recovered, as he himself had never doubted he would. I met his future wife when he was recovering and understood what her staunch support had meant to him. His long illness probably helped him a great deal to know the disease in which he later specialized, and made him the understating doctor he was. Our paths diverged, but I heard from time to time of the good work he was doing at Kelling Sanatorium, Holt, and later at Ventnor. In 1946 he was appointed medical superintendent to the Nayland Sanatorium, and it was a delight to welcome to one's own neighbourhood an old friend who, one knew, would add so much to the local fraternity. His worth was soon appreciated in the Essex-Suffolk countryside, and, though he was only with us a few years, his parting leaves an irreplaceable gap among his doctor friends. He will be deeply mourned by the past and present sanatorium patients whom he served so well. It is sad indeed that when he had won such a notable victory over tuberculosis his brave heart yielded at last to hypertension. Our kind thoughts go out to his wife and to his two children.

THOMAS LANGLES GORDON, surgeon to out-patients in the Western Infirmary, Glasgow, died in the Gardner Institute of Medicine on November 29, aged 49. Tom Gordon was educated at the Glasgow Academy and the Glasgow University, graduating M.B., Ch.B. in 1925. While he had an early leaning towards surgery, it was not until the middle nineteen-thirties that he finally adopted surgery as a career and joined the staff of the Western Infirmary. He became a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow in 1937, and a Fellow of the Royal College of Surgeons of Edinburgh in 1938. It was obvious before long that he was a surgeon of great promise. From the very outset his judgment was sound and his manipulative dexterity rapidly became of a high order. His most comforting attribute was his absolute reliability. During the second world war he was a tower of strength in the unit to which he was attached. He was an indefatigable worker, and his strong physique made him appear untiring. He was a most helpful and considerate colleague and a recognized guide, philosopher, and friend to the younger members of the staff. He was a capable teacher and a penetrating clinician. For a period he served as an examiner for the triple qualification on behalf of the Royal Faculty. He was an all-round sportsman. In his youth he excelled at rugby football (he was a notable forward for Glasgow Academicals in their halcyon days), cricket, swimming, and tennis. Later he took up golf and became a scratch player. In 1949 he was captain of the Western Golf Club at Gailles, and in that same year he had the added distinction of being the champion of the club. His untimely death came as a stunning blow to his colleagues and friends. On December 1 a funeral service was held in the David Elder Memorial Chapel of the Western Infirmary, where a large congregation of colleagues, friends, and West of Scotland golfers fully testified to the regard and respect in which he was held by the community. Mr. Gordon is survived by his wife, to whom we offer our deepest sympathy.—A. J. H.

The Services

Surgeon Lieutenant-Commander I. G. W. Pickering, R.N.V.R., has been awarded the R.N.V.R. decoration.

Brigadier (Temporary Major-General) J. C. Collins, C.B.E., late R.A.M.C., has been appointed Honorary Surgeon to the King, in succession to Major-General J. M. Macfie, C.B., C.B.E., M.C., late R.A.M.C., retired.

Colonel (Temporary Brigadier) Albert Sachs, late R.A.M.C., has been appointed Honorary Physician to the King, in succession to Major-General K. A. M. Tomory, C.B., O.B.E., late R.A.M.C., retired.

Medico-Legal

DIVORCE FOR INCURABLE INSANITY

"Continuously Under Care and Treatment"

By Section 2 of the Matrimonial Causes Act, 1937, a divorce petition can be founded in England on the ground that one party to the marriage is incurably of unsound mind and has been "continuously under care and treatment" for a period of at least five years immediately before the presentation of the petition. Being under care and treatment includes detention pursuant to inquisition or order under the Lunacy or Mental Treatment Acts, or order or warrant under the Naval Discipline Act or Army, or Air Force Acts, detention under the Criminal Lunatics Act, and treatment as a voluntary patient under the Mental Treatment Act, 1930.

The Court of Appeal recently¹ had to decide the meaning of "continuously" on an appeal by a husband whose petition for divorce on the ground of incurable insanity had been dismissed. The wife first came under care and treatment on admission to a mental hospital in October, 1945. Her condition did not improve, and she was discharged and removed to a hospital in Scotland, where she remained under detention until March, 1948. She then came to London, and was within a few days admitted to hospital in Surrey, where she had remained until the petition was presented. Mr. Commissioner Bush James dismissed the petition on the ground that the wife was not under detention during the journey from one hospital to another, and therefore had not been "continuously" under care and treatment for the necessary period.

The Court of Appeal allowed the husband's appeal and granted him a decree. The Lords Justices held that the period of detention in Scotland could be added to the periods in England, and that it was not the intention of Parliament that the five-years period of detention should be broken by the removal of the patient from one hospital to another.

¹Scotsman, July 7, 1951.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Denis Haigh Marrian, Ph.D., has been appointed an Assistant Director of Research in Radiotherapeutics, from October 1, 1951.

The Raymond Horton-Smith Prize for 1950-1 has been awarded to Dr. Hugh Reginald Jolly for his essay entitled "A Study of Sexual Precocity." *Proxime accessit*: Dr. J. A. R. Miles, for his essay on "Diet and Exercise in Relation to Certain Infections."

In Congregation on December 15, 1951, the following medical degrees were conferred:

M.D.—N. C. Lendon, D. H. Mackenzie, B. F. Brearley, H. B. Dowdell.

M.B., B.Chir.—H. A. Sanford (by proxy), Patricia L. Broadhead (by proxy).

UNIVERSITY OF GLASGOW

On December 5, 1951, the degree of M.D. (with commendation) was conferred *in absentia* by diploma upon J. Vaughn, M.B., Ch.B.

UNIVERSITY OF EDINBURGH

At a Graduation Ceremony on December 14 the following medical degrees and diplomas were conferred:

M.D.—²P. F. de Caires, ¹R. McK. Fulton, ²C. E. L. Haffner, ²T. Harrison, H. Oswald-Smith, A. S. L. Rae, ¹A. R. Somner.

Ph.D.—*In the Faculty of Medicine*: D. P. Basu, M.B., B.S., A. S. Ootschoorn, M.B.

M.B., Ch.B.—Audrey N. H. Andrew (née Robertson), W. R. C. Andrew, E. S. Blackadder, F. K. P. Brydon, R. C. Buchanan, Isobel C. Campbell, G. M. Dewar, J. M. P. Dippenaar, W. F. M. Dorward, ²Margaret J. Field, P. T. Fraser, P. W. E. Hayward, R. S. Jarema, J. H. Jennings, D. F. Kerr, Margaret L. Liddell, D. W. Lyon, Mary I. McArthur, R. Macdonald, M. A.

¹Highly commended for thesis. ²In absentia.

UNIVERSITY OF DURHAM

In Congregation on December 14, 1951, the following medical degrees were conferred:

M.B., B.S.—J. R. B. Ball, E. I. Blenkinsop, R. Bruce, G. Y. Caldwell, A. I. A. Charlton, Z. H. Cywicky, J. Dixon, J. Fitzgerald, Joyce H. Hindmarsh, W. Holmes, W. E. J. Kirby, P. H. D. Lewars, J. B. Lilly, Jean M. McIvor, J. F. Mather, F. C. Pickering, I. R. Pyle, J. B. Richardson, T. M. C. Saint, W. A. Shiels, Margaret Sibson, H. Tubmen.

UNIVERSITY OF LONDON

Dr. Charles Felix Harris has been appointed representative of the Faculty of Medicine on the Senate for the remainder of the period 1950-4, in place of the late Mr. J. B. Hunter.

The following have been appointed, or nominated for appointment, or reappointment, as representatives of the University on the governing bodies indicated in parentheses: Professor W. D. Newcomb (Institute of Orthopaedics); Professor J. M. Mackintosh (London School of Economics and Political Science); Mr. P. H. Mitchiner (Royal College of Veterinary Surgeons); Dr. C. F. Harris (School of Pharmacy).

The appointment of house-surgeon to the neurosurgery department at the London Hospital has been approved for the purposes of Branch I of the M.D. examination.

Dr. Norman Henry Ashton has been appointed to the University Readership in Pathology tenable at the Institute of Ophthalmology, from January 1, 1952.

Dr. Ian Donald has been appointed to the University Readership in Obstetrics and Gynaecology tenable at the Postgraduate Medical School of London and attached to the Institute of Obstetrics and Gynaecology, from January 1, 1952.

The title of Reader in Veterinary Physiology in the University has been conferred on Hans Friedrich Rosenberg, M.D., Ph.D., in respect of the post held by him at the Royal Veterinary College.

The following candidates have been approved at the examinations indicated:

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY (DIAGNOSIS).—P. Purcell, Una Scorer, R. F. Stubbs, Tha Din.

ACADEMIC POSTGRADUATE DIPLOMA IN MEDICAL RADIOLOGY (THERAPY).—Ethel P. Johnson.

UNIVERSITY OF MANCHESTER

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—*Old Regulations*: J. R. Jaffe, D. W. Preston. *New Regulations*: J. Ashworth, F. N. Bamford, Freda A. Broadhurst, Barbara Clough, E. M. Coates, J. Cragg, L. Duggan, J. H. A. Dwek, Margaret J. Foulds, P. Fulton, P. W. Gilman, T. T. Glancy, E. N. Gold, Dorothy M. Gratton, P. G. Haddock, C. S. Hajikakou, E. G. R. Jones, R. J. Lande, J. B. Law, B. E. Marks, G. H. Mazey, Elsa M. Mellor, G. W. H. Oldfield, L. Poller, H. J. Reynolds, G. B. Ross, D. Rothwell, G. J. Ryder, F. Smith, G. F. Smith, O. T. Taylor, P. R. Ward, W. A. Whitaker, A. Withnell.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—H. S. Coulsting, M. M. Lidgate, Edith M. Thorp.

UNIVERSITY OF LIVERPOOL

The following candidates have been approved at the examinations indicated:

M.D.—K. McCarthy, I. P. Madhok, H. Roberts.

M.CH.ORTH.—W. J. Betts, P. Chandra, K. R. Daymond, G. F. Fischer, F. J. Gruar, D. R. Gunn, A. K. Gupta, M. Natarajan, J. A. O'Garra, J. S. Roarty, I. W. Winchester, W. H. de W. de Wyt.

FINAL M.B., CH.B.—*Part IV*: Jean D. Birtles, J. H. G. Brown, R. W. H. Clarke, Josephine Dec, K. M. Fraser, B. Freeman, Morilee Garside, Pamela Garside, K. C. Greenwood, F. R. Howell, Roma McDonald, J. J. D. Macpherson, Marianne A. A. Phillips, M. A. H. Rayman, S. J. Rogers, J. A. Seddon, Ellen G. Williams, D. Winter. *Part III*: Elizabeth Bownass, W. E. Cooper, G. Corney, Enid C. Davies, J. C. Denmark, A. J. Entwistle, L. A. Guile, F. B. Hartley, Margaret J. Hellaby, N. St. J. Hennessy, Joan Knowles, A. M. Laylee, I. Miller, S. Naylor, L. A. Nettleton, W. G. W. Parry, H. G. Row, W. A. Weston, A. H. Wilde, J. D. Wright.

D.P.H.—*Part I*: M. S. Boparai, D. Brahott, J. L. Cotton, Hla Han, V. Israngura Na Ayudhia, O. Jitavare, N. N. Kanyarutoke, A. R. Kennedy, E. Lutfi, Lillie L. Munro, R. Muscat, R. C. O'Grady, W. H. Parry, T. Sukhanenya, T. A. J. Thorp, K. O. Torgersen, P. H. Waage.

CERTIFICATE IN PUBLIC HEALTH.—H. Frederiksen, E. F. W. Richards.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examinations indicated:

FINAL M.B., CH.B.—C. Barwick, Audrey M. Blake, G. V. Catford, Ann M. Haines, G. J. Hillier, R. J. Hunt, D. J. A. Jarvis, June P. Lawson, Mary Motton, I. C. Murison, P. Norris, A. J. Rowland, N. Sartori, M. Sheldrick, N. C. Tricks, D. W. Trump, D. W. Wright. *In Group I completing the examination*: R. A. Iles, M. H. B. Joyce, Gillian F. Peacock. *In Group II completing the examination*: Denise G. Macleod, Antonina J. Sidorowicz. *In Group II (Surgery and Obstetrics) only*: Helena B. M. Bailey, S. H. Brown, A. G. Walker.

CONJOINT BOARD OF IRELAND

The following candidates were duly admitted licentiates in medicine and midwifery on December 7, having passed the final examination in medicine, surgery, and midwifery of the Conjoint Board of Ireland: A. S. Beilin, F. Coyne, Anita C. Doherty, J. E. Flanagan, R. F. Frost, N. L. G. Gough, Mary M. B. Hillery, B. J. P. Leahy, Maire M. P. Leahy, M. J. Murphy, Mary P. Murray, G. J. McManus, D. J. O'Kelly, E. O'Neill, D. O'Reilly, J. F. X. O'Sullivan, Katherine P. Prendiville, B. D. Quigley, Mary T. C. Rahill, M. J. Ryan, M. Ryan, W. A. Ryan, J. P. Stewart, R. A. Wade.

The following candidates have been approved at the examinations indicated:

DIPLOMA IN ANAESTHETICS.—C. A. G. Armstrong, J. C. Clarke, Patricia Delany, E. A. Frayworth, L. McArdle, J. A. McNeilly, Patricia O'Neill, J. H. Tyrrell, N. Zwick.

DIPLOMA IN CHILD HEALTH.—V. Barry, D. C. J. Carter, G. Cremer, C. P. Nanavati, W. P. O'Keeffe, K. J. Quinn, Carmel P. Ryan.

ROYAL SOCIETY

The Council of the Royal Society has appointed Alan Lloyd Hodgkin, F.R.S., to be a Royal Society Research Professor from January 1, 1952. Mr. Hodgkin will continue to work at the physiological department of the University of Cambridge on the processes of excitation and conduction in nerve.

Vital Statistics

Salmonella Minnesota Infection

A large outbreak of food-poisoning caused by *Salmonella minnesota* has occurred in Northamptonshire and the surrounding country. Several hundred people have been affected, and a man and a woman have died. The source of infection has been traced to meat pies manufactured at a pie factory in Northamptonshire. In nearly all cases the symptoms are very mild, lasting for about three days. They include headache, nausea, and diarrhoea, and the patient is often left feeling rather depressed. As is usual in such outbreaks, elderly people are more liable to show symptoms of infection than the young. The incubation period is about 18 hours.

The first case was identified on December 21, 1951. The source was traced the next day and immediate action taken. No fresh cases are known to be occurring now. The precise origin of the infection in this outbreak is not yet known—that is, how the meat pies came to be infected.

They contained meat imported from Denmark, but that cannot necessarily be incriminated, for *Salmonella minnesota* is by no means unknown in Britain. We are grateful to the Salmonella Reference Laboratory, Colindale, for informing us that on December 10 this organism was identified by the laboratory in a specimen obtained from a patient in Northamptonshire.

In 1951 this laboratory identified the organism in 23 cases before the Northamptonshire outbreak. Most of them came from Inverness and the Aberdeen area. Two fatal cases in Aberdeen were identified in October. The infection was also identified in a case in London in November. In 1950 four human cases were discovered, but no case is known to have occurred in Britain before that.

Salmonella minnesota was isolated by Dr. B. S. Pomeroy in 1936 from a three-weeks-old turkey poul in Minnesota and its characteristics were first described by Edwards and Bruner (*J. Hyg., Camb.*, 1938, 38, 716). This is the first large outbreak in Britain known to be caused by this organism.

Week Ending December 22

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,552, whooping-cough 1,819, diphtheria 54, measles 2,321, acute pneumonia 681, acute poliomyelitis 28, dysentery 422, paratyphoid fever 17, and typhoid fever 6.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1942-50 are shown thus -----, the figures for 1951 thus ———. Except for the curves showing notifications in 1951, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

The chief fluctuations in the trends of infectious diseases in England and Wales during the week ending December 15 were increases in the number of notifications of acute pneumonia 121 and measles 104, and a decrease of 200 for dysentery.

Only small variations were reported in the trends of scarlet fever and whooping-cough; the totals for these diseases were 18 and 1 respectively fewer than in the preceding week. The rise in the incidence of measles was contributed by the midland counties; elsewhere a small decrease occurred. The largest increases were Warwickshire 128 and Staffordshire 73, and the largest decrease was Yorkshire West Riding 56. The notifications of diphtheria were 12 more than in the preceding week. The largest of the local fluctuations were rises in Lancashire 9 and Warwickshire 4, and falls in Staffordshire 6 and Yorkshire West Riding 4. A small rise in the incidence of acute pneumonia was reported from every region of the country except London.

Of the 17 cases of paratyphoid fever 10 were notified in Suffolk (Stowmarket U.D. 7).

The number of notifications of paralytic acute poliomyelitis were 1 and non-paralytic cases 8 fewer than in the preceding week. The largest returns during the week were: Middlesex, 7; Lancashire 5; Cambridge, Cambridge M.B. 4; Warwickshire, Birmingham C.B. 4; Kent, 4.

A further 104 cases of dysentery were notified in Norfolk, Norwich C.B. This brings the total cases for this city up to 446 for the past four weeks. The other large returns of dysentery were London 43, Middlesex 40, Lancashire 19, County of Southampton 17, Warwickshire 13, and Northumberland 11.

Industrial Accidents and Diseases

The number of workpeople (other than seamen) in the United Kingdom whose deaths from accidents in the course of their employment were reported in November was 122, compared with 139 in the previous month and 155 (revised figure) for November, 1950. Of these deaths 16 were underground in coal mines and 23 were in building operations.

The following cases of industrial disease were notified during the month: lead poisoning 8, mercurial poisoning 1, anthrax 2, epitheliomatous ulceration 18, chrome ulceration 50; total 79. There were no deaths (*Ministry of Labour Gazette*, December, 1951).

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending December 15 (No. 50) and corresponding week 1950.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 126 great towns in England and Wales (London included), London administrative county, the 16 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 13 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

* Measles not notifiable in Scotland, whence returns are approximate.

† Includes primary and influenza pneumonia.

‡ Includes puerperal pyrexia.

Medical News

Dr. N. Gerald Horner

Dr. Horner, who was Editor of the *British Medical Journal* from 1928 to 1946, celebrated his 70th birthday on Tuesday, January 1. A message of congratulations was sent to him from the staff of the *Journal*.

Government Scheme for Refresher Courses

Many general practitioners are not aware that, subject to certain conditions which are readily satisfied, they are entitled to 22 half-day sessions of postgraduate refresher work in each academic year. This can be spent as a fortnight's whole-time attendance at a refresher course, or the period may be split up in a variety of ways, of which attendance once a week is one example. Refresher courses are organized by the universities in each hospital region throughout the country, and the fees for approved practitioners are paid by the Ministry of Health through the university which sponsors the course. Doctors attending courses under this Government scheme can claim travelling expenses. Where absence from home is necessary or a locum is needed during attendance on a whole-time course, they can claim subsistence allowance and a grant towards the expenses of a locum. These courses are advertised in the medical journals from time to time, and the postgraduate dean or director in any university will always give information on the postgraduate facilities in his region. In last week's advertisement columns will be found the programme of courses so far arranged for 1952 by the British Postgraduate Medical Federation (University of London). These courses are open to approved practitioners from any part of the country.

Chelsea Clinical Society

The third meeting of the 55th session was held on December 11, when a discussion on "The Doctor in the Magistrate's Court" was opened by Sir Laurence Dunne, the senior metropolitan magistrate, and Dr. Philip Addison, assistant secretary of the Medical Defence Union. The date of the next meeting was announced as January 15.

St. Thomas's Day Service

The 400th anniversary of the refounding of St. Thomas's Hospital was commemorated by a service held at Southwark Cathedral on December 21, 1951, attended by the Queen and Princess Alice. The Archbishop of Canterbury reminded the congregation that the cathedral was the original priory church of the hospital, which was founded for a second time in 1551 by Edward VI after it had been plundered by Henry VIII. The Bishops of Southwark, Kingston, and Woolwich took part in the service and paid tribute to various people who had helped to develop and support the work of St. Thomas's, including Florence Nightingale, who established her school of nursing in the new buildings.

Harveian Society Prize Essay

Jaundice is to be the subject for the Buckston Browne Prize Essay. The prize, consisting of a medal, together with the sum of £100, will be awarded for the best essay on the subject, and is open to any member of the medical profession registered in the British Isles or Dominions, and is limited to candidates under 45 years of age. Essays must be sent in by December 1, 1952, and further particulars may be obtained from the hon. secretaries, the Harveian Society of London, 11, Chandos Street, Cavendish Square, W.1.

American Journal of Tropical Medicine

The American Society of Tropical Medicine and the National Malaria Society have both been dissolved and are to be replaced by a new body, the American Society of Tropical Medicine and Hygiene. The respective journals of these organizations have been amalgamated to form the *American Journal of Tropical Medicine and Hygiene*, incorporating the *Journal of the National Malaria Society*.

Louis Braille

On January 6 occurs the centenary of the death of Louis Braille. He was 42, and had been blind from birth. By his introduction of the system of embossed types he made the greatest single contribution ever devised to compensate for the handicap of blindness. He actually modified a system which had been invented by Charles Barbier in 1820, and he first publicly expounded it in 1829, while his book on the subject, *Procédé pour Ecrire au Moyen des Points*, appeared in 1837. Braille symbols each consist of a series of up to six dots arranged like the dots on a domino, and giving a range of combinations enabling all the letters, punctuation signs, etc., to be represented.

Royal Faculty of Physicians and Surgeons of Glasgow

The President and Fellows of the Royal Faculty of Physicians and Surgeons held their biennial dinner in the Faculty Hall on December 7, with the President, Mr. Walter W. Galbraith, in the chair. There was a large attendance of Fellows and guests. The principal guest was the Rt. Hon. James Stuart, M.P., the Secretary of State for Scotland, and others included Dr. W. A. Alexander, Sir Hector Hetherington, Dame Hilda Lloyd, Sir David Allan Hay, and Sir David K. Henderson. Professor David Campbell, president of the General Medical Council, in proposing the toast of "The Sister Corporations," said that the Royal Corporations had become exclusive of the general practitioner, and he doubted if this was necessary or wise. It had given rise to the demand for a new College. He suggested that if the Scottish Royal Corporations wished to fulfil their function in Scotland they should consider union, with the setting up of a Scottish College or Academy of Medicine.

Fellowships in Clinical Research

The Medical Research Council invites applications for a second series of Fellowships in Clinical Research, tenable at centres in the United Kingdom during the academic year 1952-3. These Fellowships are open to suitably qualified medical graduates who desire to prepare themselves for a career in clinical research. In general, it is intended that each Fellow appointed under the scheme should be given an opportunity, as part of his training for clinical research, to study methods of research in the basic subject most germane to his particular clinical interest.

The awards will be made for a period of one year in the first instance and will be renewable annually in approved cases up to a maximum of three years in all. Stipend will be at the rate of £850 per annum, rising by annual increments of £75 to £1,000 per annum, and in addition superannuation provision will be made (or continued within the National Health Service scheme, if applicable, by arrangement with the Ministry of Health and the Department of Health for Scotland).

Candidates for these Fellowships must be medically qualified and clinically experienced, and should preferably have worked for a period in a department in which clinical research was in progress. Applicants will be invited to submit their own proposals as to type and place of work, but the Council will be glad to advise successful candidates on the selection of suitable centres of study and to assist in placing them in departments or laboratories where the desired training and experience can be obtained.

Applications must be sponsored in each case by the head of the appropriate department in the candidate's university or medical school, and an undertaking will be required that a suitable academic post in a clinical department will be available to the candidate in that institution on satisfactory completion of the period of study under the Fellowship.

Forms of application for these Fellowships may be obtained from the Secretary, Medical Research Council, 38, Old Queen Street, London, S.W.1, with whom applications should be lodged as soon as possible, and in any event not later than March 1.

French Honour

The President of France has conferred upon Mr. R. W. Raven the Cross of Chevalier of the Legion of Honour.

Emergency Bed Service: Applications and Admissions

During the seven days ending December 31 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,015, of whom 93.1% were admitted.

Wills

The Medical Research Council is to receive about £80,000 to support research on cancer, under the will of Mr. John A. Hopps, of Leicester, a director of F. Hewitt and Son, Ltd., who publish the *Leicester Mercury* and other papers.

Sir Allen Daley, who retires from the post of M.O.H. to London County Council next month, will then become part-time associate health officer to Baltimore (Maryland) for four months and will lecture in several American schools of public health.

Professor W. Melville Arnott, of the University of Birmingham, who holds a W.H.O. Senior Travelling Fellowship, is visiting centres of medical education and cardio-respiratory research in the U.S.A. during the first quarter of 1952.

COMING EVENTS**British Association of Physical Medicine**

The annual meeting of the British Association of Physical Medicine, 45, Lincoln's Inn Fields, London, W.C.2, will be held in London on Friday and Saturday, April 25 and 26.

Hunterian Oration

Dr. George Day will deliver the Hunterian Oration before the Hunterian Society at the Mansion House, London, E.C., on Monday, February 25, at 8.30 p.m.

Course on the Prostate

The Institute of Urology is holding an intensive short course on the prostate from January 14 to 25. In addition to daily lectures there will be operative sessions at St. Peter's and St. Paul's Hospitals each afternoon. Full details from the Secretary, Institute of Urology, Henrietta Street, London, W.C.2.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday

OXFORD UNIVERSITY.—At Radcliffe Infirmary, Oxford, January 7, 8 p.m., "The Use of Gelatinized Bone in the Repair of Skeletal Defects," by Dr. Wilson A. Swanker (New York).
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury Square, London, W.C.—January 7, 7.30 p.m., "The Nomenclature of Drugs," by Mr. Frank Hartley, Ph.D., Ph.C., F.R.I.C.
ROYAL EYE HOSPITAL, St. George's Circus, Southwark, London, S.E.—January 7, 5 p.m., "Convergence, Convergence Abnormalities, and Heterophoria," by Dr. T. H. Whittington.

Tuesday

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 8, 5.30 p.m., "Sarcoid," by Dr. R. M. B. MacKenna.

Wednesday

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 9, 5.30 p.m., "X-ray Technique," by Dr. C. W. McKenna.

PHYSICAL SOCIETY: COLOUR GROUP.—At Institute of Ophthalmology, Judd Street, London, W.C., January 9, 3.30 p.m., 64th science meeting. "A Preliminary Report on Some Experiments on Tritanopia," by Professor W. D. Wright; "Light- and Dark-adaptation and the Perception of Colour," by Mr. R. W. G. Hunt.

SOCIETY OF CHEMICAL INDUSTRY: MICROBIOLOGY GROUP.—At Institution of Structural Engineers, 11, Upper Belgrave Street, London, S.W., January 9, 2.15 p.m., joint meeting of group with Society for Applied Bacteriology. Symposium on Disinfectants. "The Bactericidal Action of Phenols in Aqueous Solutions of Soap," by Professor H. Berry; "A Substitute for the Rideal-Walker Test," by Dr. P. Maurice; "Some Factors Affecting the Bactericidal Action of Chlorine," by Dr. L. A. Allen; "The Antibacterial Action of Quaternary Ammonium Compounds," by Mr. J. C. L. Resuggan; "Some General Considerations Concerning the Activities of Disinfectants," by Dr. S. E. Jacobs.

YORKSHIRE SOCIETY OF ANAESTHETISTS.—At Leeds General Infirmary, January 9, 8 p.m., "The Heart and Anaesthesia," by Dr. B. G. B. Lucas.

Thursday

ALFRED ADLER MEDICAL SOCIETY.—At 11, Chandos Street, London, W., January 10, 8 p.m., "Some Problems of Homosexuality," by Dr. Erwin Popper. Discussion to be opened by Dr. A. R. Redfern.

FACULTY OF HOMOEOPATHY, Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C.—January 10, 5 p.m., "Potentized Medicines for Use in Homoeopathy—Some Points on their Preparation and Care," address by Dr. W. R. McCrae.

GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY, The Union, University Avenue, Glasgow.—January 10, 7.30 p.m., Honorary Presidential Address by Professor Stanley Alstead.

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 10, 5.30 p.m., "Histopathology of Lichen Planus and Lichenoid Eruptions," by Dr. H. Haber.

LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool.—January 10, 8 p.m., ordinary meeting. "Duodenal Ulcer," by Professor R. A. Gregory and Mr. James Moroney.

MEDICAL ART SOCIETY.—At 11, Chandos Street, London, W., January 10, 8 p.m., "The Use of Pastels," talk and demonstration by Mr. J. K. Popham. He will afterwards criticize members' work.

ROYAL ARMY MEDICAL COLLEGE.—At Lecture Theatre, John Islip Street, London, S.W., January 10, 5 p.m., "The Proper Sphere of Social Medicine," by Dr. Andrew Topping.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—January 10, 5 p.m., "The Carcinogenic Process," Imperial Cancer Research Fund Lecture by Professor Alexander Haddow.

Friday

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 11, 5.30 p.m., "Medical Photography," by the Institute Photographer.

OSLER CLUB.—At Medical Society of London, 11, Chandos Street, Cavendish Square, W.C., January 11, 7.45 p.m., History of Pneumonia Evening. "Osler and Pneumonia," by Lord Horder; "The Advent of the Sulphonamides," by Sir Lionel Whitby; "The Changing Character of the Disease," by Sir Adolphe Abrahams.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—January 11, 8 p.m., "Hypnotism and Medicine," by Mr. J. A. Gillies.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Revill.—On December 23, 1951, to Vivienne (formerly Macpherson), wife of Dr. Hugh Revill, of Snodland, Kent, a sister for Timothy.
Wyman.—On December 15, 1951, at Westminster Hospital, London, S.W., to Joan (formerly Beighton), wife of Dr. J. B. Wyman, a son.

MARRIAGES

Swan—Ede.—On December 19, 1951, at Edinburgh, Dr. Harold T. Swan to Dr. Elisabeth A. Ede.
Williams—Thomas.—On October 27, 1951, at Machynlleth, Montgomeryshire, David Lloyd Williams, L.R.C.P.&S.Ed., L.R.F.P.S., to Gwyneth Thomas.

DEATHS

Brownlie.—On December 13, 1951, at his home in Hamilton, Lanarkshire, Andrew Brownlie, M.B. Ch.B., aged 75.
Busteed.—On December 18, 1951, at 31, Glenleigh Avenue, Bexhill-on-Sea, Sussex, John Hancock Busteed, L.R.C.P.&S.Ed., L.R.F.P.S., aged 85.
Fletcher.—On December 21, 1951, Nigel Corbet Fletcher, O.B.E., M.B., B.Chir., of 166, Haverstock Hill, London, N.W., aged 74.
Gibson.—On December 11, 1951, at Banbridge, Co. Down, Thomas Jordan Gibson, M.B., F.R.C.S.Ed., aged 57.
Hugo.—On December 24, 1951, at his home in Richmond Surrey, Edward Victor Hugo, C.M.G., M.D., F.R.C.S., Lieutenant-Colonel, I.M.S., retired, aged 86.
Kelly.—On December 18, 1951, at Wareham, Dorset, William Davenport Crawley Kelly, D.S.O., M.B., B.Ch., Colonel, A.M.S., retired, aged 74.
McComas.—On December 13, 1951, at a hospital, Dorking, Surrey, Cyril Henry McComas, M.D.
Maskew.—On December 25, 1951, at The Wilderness, Langton Matravers, Dorset, Charles Henry Maskew, M.B., Ch.B., of 17, Weymouth Avenue, Dorchester, Dorset, aged 90.
Nathan.—On December 13, 1951, Nestor John Stanley Nathan, M.R.C.S., L.R.C.P., D.P.H., D.Obst.R.C.O.G., of Talke, Stoke-on-Trent, Staffs, formerly of Dewsbury, Yorks, aged 41.
Patterson.—On December 19, 1951, at a hospital, Edinburgh, William Berwick Ure Patterson, M.B., Ch.B., of 6, Magdala Crescent, Edinburgh.
Robinson.—On December 22, 1951, at Little Ghebe, Fontwell, Arundel, Sussex, Charles Allen Robinson, M.B., B.Ch., D.M.R.E.
Smith.—On December 18, 1951, at Hemel Hempstead, Herts, Frederick Hugh Smith, M.B., Ch.B., formerly of Leeds, aged 56.
Square.—On December 18, 1951, William Holberton Square, L.R.C.P.&S. Ed.&L.M., J.P., of Bridge House, Leighton Buzzard, Beds, aged 91.
Strasheim.—On December 17, 1951, at Rondebosch Hospital, Capetown, South Africa, Pietrus Albertus Strasheim, M.B., Ch.B.
Sumpter.—On December 21, 1951, at Brancaster Staithe, Norfolk, Bernard George Sumpter, M.B., M.R.C.S., aged 87.
Witney.—On December 15, 1951, Myfanwy Dyfed Witney, M.B., Ch.B., late of South India.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Seasickness

Q.—How may seasickness best be prevented and treated?

A.—L-Hyoscine hydrobromide is probably the best preventive against seasickness, although some people will be seasick whatever treatment they get and others can be prevented only from vomiting but continue to feel nausea. Hyoscine is best taken about one hour before exposure to motion, and it is less effective, though by no means ineffective, if taken five to ten minutes beforehand. It can be used to treat seasickness after vomiting has begun, but only if it is retained for a little while. The dose is 0.6 to 1 mg. This dose will cause drowsiness in some people, but other remedies also cause drowsiness, and so does untreated seasickness. The dose can be repeated at intervals of 6 to 12 hours up to a total of 2 mg. in 24 hours. If rough weather persists most people become adapted to the motion after about two days, but they soon lose this adaptation in calm weather or ashore and then treatment must be renewed. There is no evidence that seasickness remedies either hasten or delay the onset of adaptation.

Some antihistamine substances also prevent seasickness, but recent evidence suggests that they are less effective than hyoscine and, if anything, more toxic. Promethazine hydrochloride ("phenegan") is 'probably the best seasickness remedy among the antihistamine substances, and the dose is 25 mg. for adults, one to two hours before sailing.

Impulses from the vestibular apparatus are lessened if a person lies down, and people are less liable to seasickness when they do so.

All that has been said above applies also to other forms of motion sickness, although there are great differences in the way in which people respond to various types of motion.

Molluscum Contagiosum

Q.—What treatment is recommended for molluscum contagiosum? Are antibiotics effective?

A.—Individual lesions are easily removed with a small sharp spoon, and the base may then be cauterized with pure phenol or trichloroacetic acid applied on a blunt stick. No anaesthetic is needed for this treatment and recurrences are unusual. It is perhaps as well, however, to warn the patient that further lesions may be "on the way" and may require treatment in two or three weeks' time. Recently there have been three reports from America of single cases of molluscum contagiosum treated apparently successfully with "aureomycin" (*Arch. Dermat. Syph.*, 1949, 60, 629; *J. Pediat.*, 1949, 36, 797; *Pediatrics*, 1951, 7, 206).

It is of interest to note that although molluscum contagiosum seems to be auto-inoculable, case-to-case infection is not very common. Dr. B. B. Barrack, in Brisbane, has raised the question whether bird mites could be carriers of the virus.

Safe Period

Q.—Where can I find information on the reliability of the "safe period"?

A.—On p. 124 of the book "Any Questions?" The book can be obtained for 7s. 6d. (postage 6d.) from the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1.

Chronic Paronychia

Q.—Can you recommend any treatment, apart from surgical, for chronic paronychia of the fingers?

A.—Chronic paronychia is commonly due to pyogenic cocci or to monilia infection. With the former there is from time to time a discharge of pus; cultures from this may indicate a particular antibiotic, best given as general rather than local treatment. A wisp of cotton-wool saturated with pure carbolic may be packed into the sac, under the nail fold, by means of a matchstick the end of which has been tapered to a wedge shape. This is removed after an interval of 30 to 60 seconds, the object being to cauterize the infected walls of the sac. This may be followed by a fractional dose of x rays (120 to 150 r units, unfiltered, at 60 kV), and the procedure may be repeated once or twice at monthly intervals if necessary.

With monilia infection the nail fold is more swollen, "bolstered," and there is no pus, though it may be possible to express a cheese-like material. The use of aniline dyes in solution or in an emulsified ointment base together with x-ray treatment is usually effective.

In either condition there are invariably other factors demanding attention, such as a poor peripheral or "chilblain" circulation, debility or malnutrition, or unsuitable employment, particularly wet work and cooking.

Paronychia is sometimes due to ringworm fungus, when the nail is also involved, and the latter must be removed before the application of fungicides.

Calciferol and Boeck's Sarcoidosis

Q.—Calciferol, 100,000 units daily, has been recommended for the treatment of Boeck's sarcoidosis. (1) For how long may this treatment be continued? (2) What toxic effects may occur, and what are the indications for interrupting therapy? (3) Are any biochemical or other tests useful in controlling treatment?

A.—(1) The response of sarcoidosis to calciferol therapy is good. Necessary treatment may vary from a few months to a year or more, and relapses sometimes occur. Toxic manifestations are more readily provoked in patients with sarcoidosis than in those with lupus vulgaris, possibly because the patients tend to be older and the disease is more systemic. When calciferol is given by injection or in capsule, once a week in a dose of 600,000 i.u., toxic symptoms are less likely to occur than with tablets given daily in the same total weekly dose. It is unwise to give calciferol if there is any renal or cardiovascular disease.

(2) The earliest toxic symptoms are nausea, thirst, loss of appetite, abdominal pain, dehydration and pallor, headaches, and general malaise. Blood pressure and urine should be watched, and treatment should be interrupted if these symptoms arise or if albumin or sugar appear in the urine.

(3) Estimation of the blood urea is the most important guide to a toxic state. An increase in the diffusible calcium is often one of the first signs, but the investigation requires special facilities.

Toxic Reactions to P.A.S.

Q.—(1) What toxic reactions may follow para-aminosalicylic acid (P.A.S.) therapy for pulmonary tuberculosis? (2) Which should be regarded as an indication for stopping treatment? (3) A patient treated for 28 days with 18 g. daily in divided doses (one day a week without treatment) developed a generalized erythema, which took a week to subside, but with no headache, nausea, vomiting, fever, or jaundice. Was this due to the P.A.S., and should treatment therefore be stopped?

A.—(1) The most frequent and troublesome toxic reactions to P.A.S. are nausea, vomiting, and diarrhoea. Hypersensitivity to the drug, as shown by fever or rashes, together or separately, is not uncommon. Muscular weakness or heart irregularities, attributed to decrease in the serum

potassium levels, have been described but are not often encountered. Jaundice may occur, but it has not been definitely demonstrated that this is attributable to P.A.S.; most of such cases have had injections of some kind and might be suffering from homologous serum jaundice. In animals, P.A.S. has an antithyroid action, but manifestations of hypothyroidism in patients having the drug are very rare and probably occur only in debilitated subjects or children given exceptionally large doses.

(2) Nausea, vomiting, and diarrhoea can often be minimized by taking the drug towards the end of a meal and by other simple measures. In a few cases it may be necessary to stop the drug for a day or two and then give gradually increasing doses. Exfoliative dermatitis, and possibly jaundice, are probably the only indications for stopping P.A.S. permanently. Other toxic symptoms may necessitate a temporary cessation.

(3) The generalized erythema in the case mentioned is probably due to hypersensitivity to P.A.S. From the way the question is put it appears that the rash subsided without the drug being stopped, in which case there is no necessity to stop treatment now. But if the rash subsided only after the drug was stopped, then the patient should be put back on treatment. If the symptom recurs, the drug should be stopped until the rash subsides and then the patient should be desensitized. An initial dose of 0.1 g. four times a day should be increased daily, successively to 0.5, 1, 2, 3, 4, and 5 g. Exceptionally, very sensitive patients require smaller initial doses or more gradual increases.

Anticoagulants and Cerebral Thrombosis

Q.—What is the present status of the anticoagulant drugs in the treatment of cerebral thrombosis?

A.—In general, anticoagulant drugs are not advised in cases of cerebral thrombosis, for the following reasons: (1) the differential diagnosis between intracerebral haemorrhage and thrombosis may in some cases be a matter of considerable difficulty; (2) it is recognized that a certain number of patients who have a cerebral thrombosis may have a cerebral haemorrhage a week or more after the thrombosis, probably due to alterations in the arterial wall in relation to the area of cerebral softening (*Lancet*, 1948, 2, 561); and (3) in a proportion of cases of cerebral softening no actual arterial thrombosis is found pathologically although there is atheroma and reduction of calibre in the relevant arteries.

Adrenal Ascorbic Acid

Q.—What is the function of the ascorbic acid in the adrenal cortex?

A.—The function of the ascorbic acid in the adrenal cortex is not known. Decrease in adrenal ascorbic acid after stimulation with adrenocorticotrophic hormone has led many to postulate that it is a precursor of adrenal steroids. On the other hand, the fact that the ascorbic acid content of other endocrine glands (i.e., pituitary and gonads) is high has been interpreted by others as an indication of non-specific metabolic hyperactivity.

REFORM OF THE NATIONAL HEALTH SERVICE

RECOMMENDATIONS OF THE REPRESENTATIVE BODY

For the convenience of readers we list below the recommendations passed by the Special Representative Meeting on December 13, 1951. A full report of the meeting appeared in the *Supplement* of December 22 (page 269).

Recommendation 1: That an amending Act should provide for the establishment of a National Health Service Court of Arbitration to which could be referred by the Ministers or representatives of the Management or Staff Side of Whitley Council disputes on the terms of service including remuneration, without the consent of the other party, whether existing terms or new terms affecting any section or individual member of the profession; but that the proposed arbitration on remuneration should be carried to a conclusion without waiting for the passing of any amending Act.

Recommendation 2: That the Court should have power to settle such disputes.

Recommendation 3: That the terms of service settled by the Court should be legally binding and enforceable on both sides.

Recommendation 4: That the Court of Arbitration should be composed of a legally qualified independent President appointed by the Lord Chancellor on a permanent basis, with other members having special knowledge of the subject-matter and being selected, in equal numbers, by the Lord Chancellor from panels nominated respectively by the Management Side and the Staff Side of the appropriate committees of the Medical Functional Council.

Recommendation 5: That the Minister's powers to make changes by regulation in the conditions of service (including remuneration) of any section of the profession be restricted to those items which are either agreed by the medical profession or determined by arbitration.

Recommendation 6: That in Section 5 of the National Health Service Act of 1946 the words "may set aside" "may allow" and "may make available" should be replaced by "shall provide" "shall allow" and "shall make available" respectively.

Recommendation 7: That with reference to Section 5 (2) of the National Health Service Act of 1946, all maximum charges should be abolished.

Recommendation 8: That the power of any Minister to acquire compulsorily medical equipment privately owned and also professional premises be rescinded.

Recommendation 10: That the power of the Minister to prescribe by regulation the terms of service of general practitioners and to make provision for the issue of an unlimited number of certificates without payment should be repealed and replaced by the procedure recommended by the Council in Recommendations 1-5 above.

Recommendation 11: That the Third Schedule of the Act of 1946 dealing with the constitution of regional hospital boards, hospital management committees, and boards of governors of teaching hospitals be amended so as to ensure (a) a democratic procedure of election, (b) the election of not less than one-fifth of the members by the medical staff of the hospitals concerned, (c) the election of a chairman by the members.

(Amendments 43, 44, 47, 48, and 210, dealing with details of the manner of election, were referred to the Council to consider in connexion with this Recommendation, which was approved as a general line of policy.)

Recommendation 12: That the chairman of a regional hospital board should be elected by the members, such members being elected as follows:

(a) Not less than one-fifth of the total members should be elected by the medical staff of the hospitals in the region under the control of the regional hospital board.

(b) Persons elected by the hospital management committees in the region.

(c) Persons elected by the board of governors of teaching hospitals in the region.

(d) Persons elected by the university.

(e) Persons elected by local executive councils in the region.

(f) Persons elected by local medical committees in the region.

(g) Persons elected by local health authorities in the region.

(h) Persons elected by other interested bodies (e.g., nurses).

Apart from the overriding consideration of (a), the number of persons elected in the various categories should be determined by the geographical requirements of the region.

At least one of the members of the board should be a person with experience in mental health services and one

should be a public health medical officer. These two members should be over and above one-fifth of the total members mentioned in para. (a). The election of at least one general practitioner actively engaged in general practice should be assured to each regional hospital board.

The direct nomination of members by political parties as such is to be deplored.

Recommendation 13: The chairman of a board of governors should be elected by the members of the board, such members being elected as follows:

(a) Not less than one-fifth of the total membership should be elected by the senior medical and dental teaching staff of the hospital.

(b) Not less than one-fifth elected by the university with which the hospital is associated.

(c) Not less than one-fifth elected by the regional hospital board for the area in which the hospital is situated.

(d) Persons elected by the hospital management committees in the area.

(e) Persons elected by the local health authorities in the area.

(f) Persons elected by the local executive councils in the area.

(g) Persons elected by the local medical committees in the area.

(h) Persons elected by the public health medical officers in the area.

(i) Persons representing the matrons and nursing staff of the hospitals served.

(j) Persons representing other interested bodies. Apart from the overriding consideration of (a), the number of persons elected in the various categories should be determined by the geographical requirements of the area. The direct nomination of members by political parties as such is to be deplored.

Recommendation 14: That the present control exercised by regional hospital boards be modified so as to permit to hospital management committees (a) a wider measure of executive powers; (b) a greater measure of financial authority; and (c) that these committees should include representatives of the general practitioners and public health medical officers elected by the profession in the area.

Recommendation 15: That a scheme of block grants similar to the university grants system be devised for hospital grants, the grants being paid to hospital management committees with amounts for capital and maintenance expenditure to cover as long a period as possible, surpluses being carried on from year to year.

Recommendation 16: That there should be set up at all levels of hospital administration co-ordinating machinery between regional hospital boards, boards of governors, and hospital management committees, local executive councils, local medical committees, and local health authorities in the form of cross representation and liaison of all branches of medical practice in the medical aspects of hospital administration.

Recommendation 17: That Medical Advisory Committees to advise boards of governors, regional hospital boards, and hospital management committees be elected respectively by the medical staff committees of teaching hospitals, by the medical staff committees of the non-teaching hospitals in the regions, and the medical staff committees of the hospital group, statutory recognition to be given to the committees so electing and so elected. These advisory committees should include representation from the local medical committee and the medical members of the local health committee and should elect their own chairmen. Local medical committees should be recognized as advisory committees to hospital management committees on all matters affecting general practitioners. In addition statutory recognition should be given to the medical staff committees of individual hospitals.

Recommendation 18: That Section 14 (2) of the National Health Service Act, 1946, be amended in such a way as to ensure that the consultants holding appointments at the hospital affected should see the applications and the candidates and should have adequate representation upon the advisory appointments committee.

Recommendation 19: That in order to preserve for the patient adequate facilities for private treatment (1) it be made obligatory upon the Minister to set aside adequate pay-bed accommodation in all hospitals where a need can be shown to exist; (2) the charges for hospital maintenance to a patient electing to receive treatment in a private hospital bed provided under Section 5 be reduced to a reasonable level and that the right of the patient to receive free hospital accommodation under the Act should be recognized by allowing him in effect a grant-in-aid for accommodation in a private bed, should he elect to receive treatment from a registered medical practitioner in a disclaimed hospital or in a registered institution. (As far as possible the charges for maintenance in private beds should be standardized as between one hospital and another in each hospital group.)

(The abolition of amenity beds was referred back to the Council.)

Recommendation 20: It should be embodied in the Act that local authorities must exercise their powers of co-option to secure the inclusion in the Statutory Health Committees appointed under Section 19 (3) of the Act of not fewer than two medical practitioners representative of the local medical profession selected from among those nominated by appropriate local medical committee(s). Part-time employment by the local authority should not be a bar to co-option.

Recommendation 21: That the proviso in Section 10 of the National Health Service (Amendment) Act, 1949, be amended to read as follows:

Provided that the remuneration to be paid under such arrangements to a practitioner who provides general medical services shall, with certain exceptions to be agreed with representatives of the profession, be by capitation fee or by item of service or other method of remuneration except that it shall not be by fixed salary and it shall not be possible to vary this arrangement except by amendment of the Act preceded by proper consultation with the profession. In the event of any disagreement, such consultation shall be followed by arbitration as laid down in Recommendations 1-4.

Recommendation 24: That Section 38 of the National Health Service Act, 1946, be amended to such extent as is necessary to entitle patients obtaining their medical care privately to obtain drugs, spectacles, and appliances at the public expense on the prescription of the attending practitioner on Form E.C.10 or any other necessary form, and any other hospital services including pathology, x rays, and physiotherapy on the same terms as patients registered in the National Health Service, and that doctors treating private patients with State drugs and appliances be subject in those matters to the normally accepted discipline.

(A parallel resolution for the supply of surgical appliances now supplied through the hospital service on Form A.O.F.2 of the Ministry of Pensions was also passed.)

Recommendation 25: That the National Health Service Regulations be extended so as to provide disciplinary arrangements for the patient and that where it appears that a complaint to a medical services subcommittee has been found to be unjustifiable, frivolous, vexatious, malicious, or fraudulent the subcommittee shall have the power to recommend and the Minister to order that the expenses of the subcommittee, respondent, and witnesses be defrayed by the complainant.

Recommendation 26: That the Minister and the Association should draw up a code of conduct for patients and that the Minister should take determined steps to bring it to the notice of every patient at regular intervals.

COMPENSATION

Section 36 of National Health Service Act, 1946

The Ministry of Health announces that the rate at which compensation will be payable, expressed in years' purchase, is 1.5847. This figure is the result of dividing the global sum of £66m. by the total of all assessments which is referred to in the regulations as "the aggregate annual loss."

All doctors entitled to compensation have been notified of their assessments, and the Ministry will inform each doctor as soon as possible of the exact sum, calculated to the nearest pound, which will eventually be payable to him. In the interest of the doctors themselves, therefore, absolute accuracy in the calculation of these sums is essential. Careful scrutiny and cross-checks will be necessary, and this is bound to take some time. Meanwhile doctors will be able, without difficulty, to apply the above factor to their own assessments.

In notifying practitioners of the amount of their compensation priority will be given to those doctors who have retired and the representatives of those who have died. In these cases payment of the whole or balance of the capital sum due to them will be made as soon as possible. There will be no need for them to submit any further application.

The consequential adjustment of the interest provisionally paid on the capital sum will also be made as soon as possible.

GENERAL MEDICAL SERVICES COMMITTEE THE FORTHCOMING ADJUDICATION

A meeting of the General Medical Services Committee was held on December 20, 1951, with Dr. S. WAND in the chair. Dr. W. Neil Darling, of Edinburgh, was appointed to fill a vacancy among the Scottish members on the Committee, and Mr. D. C. Bowie was appointed as a co-opted member. Two representatives of the Assistants and Young Practitioners Subcommittee, Dr. A. Joffe and Dr. A. D. Manning, were also co-opted. The new members were welcomed to the meeting by the Chairman.

It was formally reported that Mr. Justice Danckwerts had been appointed adjudicator in the forthcoming arbitration on remuneration; also that counsel, led by Mr. J. Millard Tucker, K.C., to represent the profession's case, were now being instructed. The Committee would be called together later for the special purpose of considering the evidence, and it might be that this would occupy more than one day.

A resolution from the Liverpool Local Medical Committee professed serious disturbance at the lack of information received in regard to the question of the arbitration. The Liverpool representative, Dr. GIBBONS, also pressed that, without awaiting the result of the arbitration, an interim payment should be made to practitioners based on the revised figures for population. He said that the *per capita* payments had steadily dropped in his area during the last two years. After some brief discussion a resolution of confidence in the Distribution Committee was carried without dissent.

In reply to Dr. CARDEW, the CHAIRMAN said that any retrospective payment must obviously follow the old lines of distribution. Dr. Cardew wanted it established that retrospective payment depended in no way whatever on an agreement on a method to be applied in the future. Dr. HOWE WOOD said that they were all agreed that the inquiry should determine not only the extent to which they were underpaid but what their underpayment had been during 1950, 1949, and the last six months of 1948. This having been accepted, it should be possible to disentangle the sums in respect of those years and to reimburse the practitioners who had actually done the work and earned the money which they had so far been denied. Dr. DAVIES suggested that when the final adjudication was made the Working Party should be requested to attempt to separate

from the award the appropriate amount for back payment and to consider the best method of distributing it on behalf of those who had earned it.

It was agreed that the matter be referred to the Working Party for consideration and action at the appropriate time.

Inflation of Doctors' Lists

A letter was read from the Birmingham Local Medical Committee expressing dissatisfaction at the means adopted by executive councils to attain the desired end of "cleansing" doctors' lists. Birmingham was not convinced that the letter addressed to patients was in every case reaching the hands of those for whom it was intended. It was also considered very undesirable that, where an executive council had received no reply to its communication, doctors should be required to call at the addresses; conceivably it might expose them to a charge of canvassing.

The CHAIRMAN said that the whole of these difficulties had been raised with the Ministry, and as a result he could promise that a number of changes would be made in the present arrangement.

The Committee proceeded to discuss a number of recommendations on action to be taken in furtherance of some 60 or more matters which were the subject of resolutions at the recent Annual Conference of Local Medical Committees. One of these concerned the provision of diagnostic facilities for practitioners, and had already been conveyed to the Ministry with an intimation that in many parts of the country diagnostic facilities were not yet available to the general practitioner direct and asking for increased support in meeting this need. Measures were discussed for bringing to the notice of hospital authorities the necessity for this provision.

Public Relations

The proposals made at the recent Annual Representative Meeting for an enlargement of the Public Relations Committee were considered. Dr. BREACH said that one possible source of difficulty in public relations was that at a certain stage the matters which were being pursued by representatives of the Association or of the Committee were fully publicized and a considerable measure of enthusiasm aroused, and then, for the excellent reason that negotiations were proceeding, nothing further was published for weeks or months, and those concerned in the negotiations were apt to forget that those outside were not aware that these were in progress.

Dr. DAIN, Chairman of the Public Relations Committee, pointed out that the function of the Public Relations Committee was the mechanics of putting Association policy to the public; the publication of these policies within the profession itself was the work of the medical secretariat and the *Journal*. It must not be thought that everything of a publishing nature must be done through the Committee because it bore the title of "public relations."

Eventually it was agreed to recommend to the Council that the number of members of the Public Relations Committee should not exceed twelve, four of whom should be appointed by the General Medical Services Committee.

Filling of Vacancies

The Annual Conference did not accept the Committee's recommendation concerning the filling of vacancies. The Committee had recommended that the terms of service should be amended in order to protect the position of a successful applicant to a practice vacancy who found that the practice premises had been secured by another doctor. The refusal to accept was mainly on the ground that this would be a still further restriction of freedom. Owing to an unfortunate working out of the rules of procedure, Dr. WAND had not been able to put forward at the Conference the case for the recommendation, and he now addressed to the Committee the observations he would have made, in which he pointed out that there was an essential difference between granting freedom to the incoming doctor who had

secured the practice by the established machinery and to the "pirate" who had succeeded in thwarting that machinery at the expense of the successful applicant. He invited those who objected to the method to put forward counter-proposals, at the same time reminding the Committee of the element of urgency in this matter.

It was agreed after a brief discussion to constitute a small subcommittee, including a representation of the Assistants and Young Practitioners Subcommittee, to consider any counter-proposals, with a view to bringing forward the whole matter for final decision at the next meeting of the Committee.

Much other business on the day's agenda included a consideration of the memorandum of evidence proposed to be given by the Society of Medical Officers of Health to the committee of the Central Health Services Council appointed to study general practice; a report by Dr. Gray from the Committee on the Association of General Practitioners and Hospital Work; the minutes of the G.M.S. Subcommittee (Scotland), and other correspondence and resolutions from local committees. The representative of the British Dental Association on the Committee (Mr. Gilbert) reported that his association had decided to establish a General Dental Services Committee as a standing committee of its representative board, and a place on the Committee was allocated to a representative of the British Medical Association. Dr. Frank Gray was nominated for the position.

CONSULTING PATHOLOGISTS GROUP COMMITTEE

At the meeting of the Group Committee on October 26 Dr. J. G. GREENFIELD was appointed chairman for the session 1951-2. Dr. E. N. Allott, Dr. S. C. Dyke, and Professor R. J. V. Pulvertaft, who had been re-elected to the Committee after their retirement at the end of last session, were cordially welcomed back. Dr. Allott was reappointed the Committee's representative on the Central Consultants and Specialists Committee.

Retiring Age and Superannuation

Dr. A. G. SHERA, of Eastbourne, attended the meeting for the discussion of a letter which he and others had sent to the Group Committee calling attention to a hardship which confronts pathologists approaching retiring age. Having for the most part been attached to voluntary hospitals before the appointed day with no superannuation scheme, they have no previous service which may be reckoned in the assessment of their pension.

Another problem which the Committee considered at the same time was the difficulty in filling consultant posts in pathology. It was pointed out that, whereas in other specialties there is an ample supply of medical men and women waiting to be absorbed into the consultant grade, the reverse is true of pathology; and often when a consultant post is filled a gap is created elsewhere in the specialty.

Extension of Contracts

The Committee felt that both these problems would to some extent be solved if for the time being pathologists could have their contracts extended on reaching retiring age, and it was decided to recommend that representations be made to the Ministry that regional boards be asked to consider exercising their discretion, under para. 15 of the Terms and Conditions of Service, to do this.

In regard to honorary contracts, which may be granted under para. 15 (2) of the Terms and Conditions, it was pointed out that these were valueless unless pathologists had access to laboratories. There had been at least one case of difficulty in this connexion. The Committee was strongly of the opinion that an honorary contract should carry with it the right to use a laboratory, and that this was implied in para. 15 (2).

Pension for Services

On the question of pension, in the Committee's view the elderly pathologist with a considerable amount of voluntary-hospital service to his credit who immediately before the appointed day was attached to voluntary hospitals for more than 50% of his time should be afforded some pension in respect of his services. The Committee decided to ask the Compensation and Superannuation Committee to raise this matter with the Ministry in conjunction with the problem of the elderly general practitioner with previous service as an N.H.I. practitioner, for whom that committee is endeavouring at the request of the Representative Body to negotiate a similar concession.

The present position under the Superannuation Regulations is that an officer who was transferred under the N.H.S. Act from a voluntary hospital where there was no superannuation scheme may count his voluntary hospital service as qualifying service—i.e., service which may be added to N.H.S. service—only if necessary to make up a minimum qualifying period—e.g., 10 years for pension: it does not affect the actual amount of his N.H.S. pension. A few officers, although not in a pension scheme before the appointed day, nevertheless had reasonable expectations of receiving superannuation benefits from the voluntary-hospital authority on retirement, and in such cases the Minister may make payments supplementary to their N.H.S. pension.

Difficulty in Securing Pathologists' Services

Consideration was given to a suggestion of the Law Society, referred to the Committee by the Association of Clinical Pathologists, that in view of the difficulty in obtaining the services of pathologists a list should be prepared of those who are willing to conduct post-mortem examinations or to give evidence on behalf of persons charged or likely to be charged with criminal offences. The Law Society also sought advice on appropriate fees for pathologists' services in legal aid cases.

The Committee agreed to call a meeting, under the chairmanship of Dr. J. G. Greenfield, to discuss these matters, and to invite the Association of Clinical Pathologists, the Association of Pathologists, and the Medico-Legal Society to send representatives.

Form for Post-mortem Reports

The Committee had been invited to consider drawing up for the benefit of coroners a standard form which pathologists could use when reporting on post-mortem examinations.

The Committee was not in favour of having a detailed form, and indeed it was considered impracticable to draw up such a form which would be appropriate for all examinations. There was no objection, however, to a form which would cover the essential points common to all examinations, provided that the information recorded was strictly confined to the facts observed in the examination and the cause of death as shown by these facts. Other information—e.g., an opinion on the cause of death where this is not evident from the facts observed—should be given separately.

Since the meeting a suitable form has been devised in consultation with the members of the Committee and has been submitted to the appropriate quarter.

Other Matters

The Group Committee decided to support the Tuberculosis and Diseases of the Chest Group Committee in its request that the staff side of Whitley Committee B should continue to press for allowances to whole-time officers towards car and telephone expenses, subscriptions to learned societies, and the cost of medical textbooks and periodicals, and if necessary to refer the matter to arbitration.

It was reported that the Central Consultants and Specialists Committee (Scotland) still had under consideration a resolution

of the Group Committee viewing with concern the fact that all appointments in Scotland in pathology were whole-time, and there were thus no pathologists available for private work or entitled to receive remuneration for domiciliary consultations. The Committee requested that the attention of the Central Consultants and Specialists Committee (Scotland) again be called to the matter.

The Committee expressed support for efforts which are being made to raise the status of animal-house attendants, with the object of attracting more suitable candidates to these posts.

Consideration of a number of applications for Group membership had to be deferred owing to lack of time. At the next meeting the Committee will review the criteria of membership and the name of the Group.

Other matters to be discussed at the next meeting of the Committee include fees for pathological services outside the scope of the N.H.S., and the items of service which may properly be regarded as outside the scope.

THE F.F.M. AND THE B.M.A.

The keynote of the speeches at the dinner held by the Fellowship for Freedom in Medicine on December 13, 1951, was that the Fellowship was not antagonistic to the Association. In the opening speech Dr. J. A. GORSKY said, "I am and always have been a loyal member of the B.M.A." The force of their criticism, he went on, was in direct proportion to their loyalty to the Association and to the profession. After reference to Mr. Bevan's pledge (not fulfilled) in May, 1948, that he would discuss any amending Bill fully with the profession before introducing it, Dr. Gorsky observed that amendments must be so far-reaching as to change fundamentally the nature of the Service. He acclaimed the fact that the Amending Acts Committee was now a standing committee of the B.M.A. Its chairman was a member of the F.F.M.; the Fellowship could justly pride itself on the results of the interim report on amending the Act. The Fellowship was always striving for unity of the profession. It recognized that the whole concept of the N.H.S. was based primarily on the hospital service, the role of the G.P. being subsidiary—the N.H.S. was thrown out of balance at the outset.

Dr. E. C. WARNER, praising the leadership given the Fellowship by Lord Horder in the autumn of 1948, said that to-day they had 3,163 medical members. The first three objects of the Fellowship were: "(1) To insist on the preservation of the highest standards of medical practice. (2) To protect the public and the medical profession from State monopoly in medicine. (3) To define the limits of State medicine so as to protect the rights of the public and of the medical profession in relation to all types of independent practice." They recognized that some kind of national health service had come to stay—"Let us bend all our energies to alter it and amend it so drastically that it can be made workable." The Fellowship believed that those practitioners who wished to do so should own the freehold of the goodwill of their practices. To prevent State monopoly in medicine the Fellowship would encourage every form of independent practice outside the N.H.S. General practitioners must be given the status, the time, and the opportunity to be the family doctors and the family friends of their patients. They deplored the expulsion of general practitioners from general-practitioner hospitals, and had supported the Kingston doctors in their fight.

Dr. M. H. F. COGLEY pleaded for the establishment of more group practices where general practitioners could have available miniature pathological and radiological services. "Such a group should have available to them all the diagnostic aids available to a hospital out-patient clinic."

Dr. R. HALE-WHITE said that the aim of the Fellowship was to secure conditions "in which doctoring can flourish to the best advantage of the public." Before the N.H.S. came into being many of them had realized that the great

danger was that the State would come between them and their patients in a way that would interfere with the doctor-patient relationship. In the relationship between medicine and the State they should see to it that they were not divided into little groups of this and that. "For we are all doctors and unity is of the very first importance in all our dealings with the State."

MEDICAL OFFICERS OF HEALTH RELAXATION OF CONTROL

Various ways in which the Minister of Health should relax control of medical officers of health are set out in the second report of the Local Government Manpower Committee (H.M.S.O., 1s. 6d.). The report has been approved by the Government.

It states that the requirement of the Minister's approval to individual salaries of medical officers of health and salary variations should be revoked; they should be replaced by a general provision requiring salaries to be paid in accordance with nationally recognized scales.

The Minister's approval should no longer be required for appointments of medical officers of health made in accordance with the arrangements formulated by county councils under Section 111 of the Local Government Act, 1933 (or in London in accordance with a plan for the joint appointment of borough medical officers of health when formulated for the county). The requirement to report vacancies to the Minister should be dispensed with, and there should be no obligation to obtain the Minister's approval to proposals for filling a vacancy before advertising it.

In place of the present provision requiring the Minister's consent to any alteration in the terms of engagement of an individual officer there should be substituted a provision that an officer aggrieved by the alteration of the terms of his engagement may appeal to the Minister. Control over dismissal should be retained by the Minister.

Heard at Headquarters

The Press and the S.R.M.

Nearly every newspaper in the country seems to have had something to say about the Special Representative Meeting, and at the meeting itself there was a record attendance of Press representatives. Many of the papers devoted leading articles to discussing the proposed reforms, as well as giving substantial reports of the meeting in their news columns. As would be expected, to most of the national dailies the principal feature of the meeting seems to have been the proposed code of conduct for patients. None of them liked it very much, and the *Daily Express* even had as its main headline, "Now Punish Patients." Most of the provincial newspapers, on the other hand, selected for their headlines subjects that doctors may think to have played a more important part in the meeting, though very few discussed at any length the main items on the morning's agenda—namely, the independent court of arbitration and its constitution.

Inky Drop

On the whole the publicity was both well informed and favourable to the doctors' contentions, though mingled with plenty of fair criticism. But there was no favourable publicity about the code of conduct, which the *Birmingham Mail* described as a fatuous proposal "all nicely calculated to antagonize public opinion." Certainly this drop in the ocean of the agenda, when converted into printers' ink, has spread through and coloured some of the publicity given to the meeting. Papers that discussed the main reforms at length in leading articles included the *Manchester Guardian*, *The Times*, the *Scotsman*, and the *Yorkshire Post*. The first two were among the few newspapers which carefully analysed the profession's apprehensions about the

powers of the Minister of Health and the proposals for limiting them. Both were doubtful whether the policy would ever be acceptable to the Government.

Constitutional Powers

After saying that there would be sympathy for the reasons which had driven the B.M.A. to call for a statutory arbitration tribunal, *The Times* added that legal experts would argue fiercely about what would become of the sovereignty of Parliament if such a law were passed. "The B.M.A. and the Ministry are both committed to arbitration in accordance with an agreed procedure in case of dispute. They have failed after protracted argument to agree on a procedure and conditions of arbitration—except for *ad hoc* arrangements for dealing with one dispute. It is difficult to believe that the matter could not be settled voluntarily by a display of good will on both sides."

The *Manchester Guardian*, after drawing attention to the great importance that doctors attach to the principle of compulsory arbitration before a tribunal independent of the Government, goes on: "The B.M.A. is on sound ground in arguing that . . . the Minister, if he retains the final decision on terms, is acting as a judge of his own cause. But there was something in Mr. Bevan's contention, too, that he could not discharge his responsibility to Parliament if such questions as terms of service determining the public cost of the scheme were taken out of his hands. It will be interesting to see whether Mr. Crookshank finds it possible to accept the limitation on his constitutional powers which Mr. Bevan so vigorously repudiated."

The S.R.M. was a stiff dose to administer to the public in daily newspapers, but the Press gave it in full measure and much valuable publicity was gained.

General Practitioners and Hospitals

Mr. Sangster Simmonds, in his presidential address to the West London Medico-Chirurgical Society, put forward a mass of ideas, deriving from his recent visit to the United States, on the subject of general practitioners and hospitals. But although discussion was invited only one member, and he a general practitioner, joined in. Mr. Sangster Simmonds suggested an experimental unit in the form of a general hospital comprising a medical school for undergraduate and general-practitioner postgraduate students, one or more general-practitioner clinics with simple equipment, and a registrar consultation clinic for patients needing a fuller examination than a general practitioner had time or equipment to give. The general practitioner who took part in the debate declared that two rather different things were needed to re-establish the family doctor under the National Health Service. One was more nursing and clerical help for the doctor in his own consulting-room and surgery. The other was not registrar consultation clinics at hospital, nor minor ones for general practitioners, but the generous provision of diagnostic facilities at hospital. The general practitioner, he said, could often draw his own conclusions from the pathological report or the x-ray picture, and if he then needed more help he could ask the consultant to assist him. Such a plan would not only give the patients a better service but would make the general practitioner a better doctor. The added responsibilities of the general practitioner would themselves bring the necessary endowment to cope with them.

Voluntary Spirit Not Dead

Not so long ago people were exclaiming that the National Health Service Act had killed the voluntary spirit, at least so far as hospitals were concerned. But Dr. Godber, Deputy Chief Medical Officer of the Ministry of Health, reminded a conference in London the other day that there were 450 hospital boards and management committees in this country, and he estimated that there must be at least 10,000 people engaged in serious and continuous voluntary work on behalf of hospitals, giving up their time to these labours without reward, many of them inspired by a tradition of public service and others by a pity for hospital sufferers.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Amenity Beds

SIR,—The medical profession is being forced into a wrong position on the question of amenity beds. As doctors we warmly welcome every practicable amenity for our patients that does not interfere with medical treatment. If, for example, it were possible from economic, organizational, and nursing standpoints for all hospital beds to be composed of single-room units, we should welcome this course to the extent that our patients felt it to be an amenity. For some categories of patients—for example, children—some increased segregation is very desirable on medical grounds. Our anxiety about amenity beds under present circumstances is that often they are not used to the best advantage of our patients as a whole. With the majority of patients nursed in wards, and a comparatively very small number of single-bed units, the demanding of one of these units as a right in return for a nominal charge may prevent our using them for such purposes as an emergency admission in the middle of the night, a patient who disturbs a ward at night, or a dying patient.

The present situation should be dealt with not by abolishing the principle of amenity beds (on the contrary, within the limits of what is practicable, they should be increased), but by abolishing the nominal charge for amenity beds. In this way the beds could be used primarily for the amenity of our patients as a whole, and secondarily to meet the wishes and natural susceptibilities of individual patients. With the full co-operation of the medical profession in dealing with the amenity bed question on its merits, we should be entitled to demand that the question should not be used as a backstairs attack on the principle of independent non-State medical practice.—I am, etc.,

London, W.1.

DAVID H. PATEY.

Tracing Patients

SIR,—Dr. Cyril Shepherd (*Supplement*, December 22, 1951, p. 284) has taken me to task for my strictures upon Dr. Bladon and himself. He points out that he has been able to trace at least 60% of his missing patients. I must therefore concede him the point that I was wrong when I suggested that it would hardly be worth while trying to trace many of the listed patients. I am, however, unable to find anything in his original letter which suggests in a positive way that he realizes "the absolute necessity of conducting this purge," and Dr. Bladon, for his part, seems to feel that if the problem cannot be solved by the authorities without the help of the doctors there is nothing further to be done about it.

The main stimulus that provoked me into writing my original letter was the fact that, whenever doctors are asked to do anything to help the authorities to organize things better, there is always an outcry somewhere that we are being unreasonably put upon. In this case the doctors concerned have, after all, managed to assist the local executive council to trace a large number of persons who, for one reason or another, could not be contacted in other ways. They have thus performed a service of considerable value to the efficient functioning of the N.H.S., which I venture to suggest, at the risk of being considered even more schoolmasterly, they might have done in the first place willingly and in a co-operative spirit.

I wonder incidentally what Dr. Shepherd would have said if he had been sent a list of those 200 patients who have not been traced with a notice saying that, as they were presumably no longer resident locally, they would be removed from his list forthwith without his being given an opportunity

to try to locate them. After all, he agrees that the purge is absolutely necessary and he cannot really have it both ways.—I am, etc.,

Margate.

M. CURWEN.

SIR,—I have received a list of names and addresses of my National Health Service patients whom the executive council is unable to trace, and a request to supply any information I have concerning these patients. Failing any information being given, these patients' names will be removed from my list in a short time.

My object in writing is not to raise the question whether general practitioners should be put to the trouble of carrying out this investigation (this matter has already been ventilated in your correspondence columns), but rather to stress the importance of doctors examining the list carefully when they receive it.

An analysis of the names gives the following categories under which the patients fall:

- | | |
|--|-----|
| (1) Patients who have moved to a new address which is known to me and who have received medical attention recently | 42% |
| (2) Patients who have moved to a new address which is known to me but who have not received medical attention recently | 23% |
| (3) Patients about whom I have no information | 19% |
| (4) Patients who can be presumed to have died | 14% |
| (5) Patients whose names have already been removed from my list | 2% |

I think that I can reasonably assume that, in view of the information which I am able to give to the executive council, practically the whole of categories (1) and (2)—viz., 65%—will not be removed from my list of patients. I happened to notice that in category (4) there are quite a few patients who, if still living, are well over 100 years of age.

As I have no reason to think that my list is other than average, I feel that doctors would be well advised to peruse their lists carefully when they receive them.—I am, etc.,

Swinton, Manchester.

JAMES O'GRADY.

SIR,—There is little doubt that all members of the medical profession will agree with the Coventry doctors (*Supplement*, November 24, p. 231) and join with them in their protests against having the onus of tracing patients put on to them as an extra burden to their already onerous duties. Dr. M. Curwen defends this imposition (*Supplement*, December 8, p. 258), but I wonder if he has ever had this task to do.

When I was appointed to a practice two years ago I soon received some special E.C. 22 A forms informing me that some 52 patients had been removed from my list (not transfers to other doctors). It so happened that at the time I was treating some of these persons, and neither they nor I could understand why they had been removed from my list. They were in possession of medical cards with the name of my predecessor thereon, and I was in possession of the medical records for these persons. I have never been able to find out the real cause of their removal. In order to save my list I was put to the trouble of tracing these persons, which proved no easy task, as it was not ethical to approach them and ask them if they wanted to remain on my list. By tactful means in time I managed to get in touch with several of them, mainly when members of their family came to the surgery, but there were many whom I was unable to approach. It was necessary to get these persons to fill up new E.C. 1 cards, and in the majority of cases, while they were willing to do so, they were angry that they should have been removed from my list for apparently no reason whatsoever.

Only recently I received another E.C. 22 A from the executive council, and among the names thereon were three of the very persons who had signed E.C. 1 cards two years previously when they had been taken off my list. These persons once again were indignant that they should be removed, and, I believe, wrote to the executive council voicing their protests.

As well as the list which I received as stated above, I later received from the executive council about 100 or more

slips, each stating that the usual letter which is sent when a new doctor takes over a practice had been returned by the post office as they had been unable to trace the addressee, and unless I could notify the executive council of the whereabouts of these persons within six months they would be removed from my list. Another task for me—that is, if I did not want my list diminished by 100 or more.

In the area where I practise there are continual movements of the residents, some to other addresses in the area, others to addresses in adjoining areas and within reach of my surgery, and these persons do not notify me till they come at some later date for treatment. Yet the task of knowing their addresses, or their new names if they have married, is put on the poor doctor when even their next-door neighbours do not know their new address.

Has anyone ever tried to trace anyone from an electoral register? I tried to trace some of my "missing patients" and soon gave up the uneven task. I even asked the food office if they would help, but met with a blank refusal. How, then, is the doctor to trace these missing patients? Perhaps Dr. Curwen will enlighten the profession, as he so strongly upholds the "purge" and the onus being put on the G.P.

No doctor wishes to get paid for someone who is dead, or who has changed to a doctor in another district, but when a patient has registered with a doctor that doctor should receive credit till the machinery of the registrar of deaths notifies the executive council of the patient's decease, or the machinery of the executive councils gets a notification that a patient wishes to be transferred to another doctor or moves to another district and registers with a doctor there. Is this "purge" a confession of the failure of the executive councils that their system of working has broken down?

There are very many persons who go to another area and do not register with the doctor there till they need treatment, and vice versa there are patients in the first area who have come to live in the former area and who likewise have not registered; this balances out matters. The onus of tracing patients who have been and are registered with the executive councils as on the list of a doctor should rest with the executive councils, and this new task should not have been placed on the profession.

Does this new burden have the blessing of the B.M.A.? Was the B.M.A. consulted before the "purge" was started? And did it agree that one more burden should be added to the G.P.'s duties? The B.M.A. is the organization which exists for the protection of the profession and should strongly oppose any oppression, but if it has been consulted why does it in this imposition turn a blind eye?

What the medical profession will be asked to do next unless some steps are taken to relieve the general practitioners from existing burdens is a matter of conjecture, but I join the Coventry doctors, as do many other members of our profession, in protesting against being turned into private inquiry agents, even if it is to save our lists. The keeping of correct lists is the duty of the executive councils, and this should be their responsibility alone.—I am, etc.,

London, S.W.18.

C. J. SHORTT.

SIR,—As a doctor having 38 years' experience in general practice, I feel I am conversant with many changes that have taken place during my lifetime, and so I was interested in the letters of Drs. C. Shepherd and D. M. Bladon (*Supplement*, November 24, p. 231) and the reply of Dr. M. Curwen (*Supplement*, December 8, p. 258) and his attempt to forestall any outcry against the purge being carried out by the Ministry.

I would like to say to Dr. Curwen that I believe no honest practitioner is aggrieved at the removal of dead persons or persons proved by the Ministry to be no longer a risk in his area, but certainly he is aggrieved by the removal of persons whom they only assume are no longer living in his area and may at any time be a risk. I have come across several cases in my practice of this assumption and their consequent removal. I would ask Dr. Curwen if the respective Ministries of England and Northern Ireland will reimburse the doctors for the periods these persons have been removed.

Surely the time and money spent in intensive study by the average student—about seven years—is deserving of work better worth while, and surely a panel doctor's leisure time should be relegated to building body, mind, and soul and freed from this iniquitous imposition.

It would be interesting to know how the Commissioners of Inland Revenue keep trace of all the folk liable to income tax. If one happens to remove from his address, does he cease to pay income tax because he has omitted to inform the authorities of his whereabouts? If it is the business of tax authorities to trace their clients, is there any reason why another Government department should be less efficient?—I am, etc.,

Belfast.

DAVID CALWELL.

Prescribing in the N.H.S.

SIR,—Since the beginning of the National Health Service it has been apparent that the great increase in the general practitioner's work is due to the requirement that he must write a prescription for every item of drugs or dressings used by his patients. If a satisfactory solution of the repeat-prescription problem could be found it would be worth all the reforms suggested by the Amending Acts Committee put together.

With things as they are, the demand for prescriptions will inevitably increase. Many people are only now beginning to realize how much can be obtained on a doctor's prescription. As a result our surgeries are thronged, the drug fund soars, and in inverse proportion our time available for diagnosis diminishes.

Most doctors would agree that vast economies could be effected in the drug bill without any very great loss in therapeutic value. It is equally obvious that any practicable scheme to do so must necessarily be a national one.

I have two suggestions to offer: either (a) to return to the N.H.I. system, wherein proprietary medicines were not allowed, except in those instances where there was no B.P. equivalent; or (b) for the Cohen Committee to occupy itself in drawing up a list of therapeutically indispensable drugs which can be prescribed under the National Health Service. All other medicines, flavouring agents, elegant proprietaries, etc., could still be prescribed by the doctor without hindrance, but the patient would be required to pay for those himself.

I favour the latter solution. It would be unlikely to cause hardship. It would ensure better value for the public money spent on the drug fund. Above all, it would free the general practitioner from an intolerable burden and thereby arrest that fall in status which is being deplored on all sides.—I am, etc.,

Thornton, Fife.

JAMES B. FLEMING.

Health Service Discipline

SIR,—Dr. R. W. Cockshut's letter (*Supplement*, December 29, 1951, p. 291) is long overdue. There are so many open pitfalls to any medical man these days that the possibility of further dangers to us all from unwritten regulations should be met at once. I hope that Dr. Cockshut's letter, which expresses clearly the sentiments of most of us, will induce many to write to you.—I am, etc.,

London, E.15.

H. J. HARCOURT.

Vetting Local Authority Posts

SIR,—I note that, when certain hospital appointments are advertised, applicants can visit the hospitals and clinics concerned and that this does not constitute canvassing. I feel that local authorities should insert a similar clause in their advertisements for public health staff. Local authorities go to considerable trouble to vet their applicants, and I feel that applicants should be given every opportunity to vet the local authorities when they apply for posts.

If this procedure was adopted, progressive local authorities who provide good facilities for medical staff, and a high standard of service to the public, would get the best applicants. In time local authorities with poor facilities and indifferent services would either have to improve conditions to attract medical staff or remain understaffed.—I am, etc.,

Caernarvon.

G. W. ROBERTS.

Compensation

SIR,—I understand from a question in Parliament on December 6, 1951, that there are at least a dozen practitioners who for various reasons have not established with the Ministry of Health their claim for compensation for loss of the selling right of the goodwill of their practices. As one of those so affected, I should like to get in touch with the others, if they would communicate with me at the address below.—I am, etc.,

66, South Street,
Ponders End, Middlesex.

Branch and Division Meetings to be Held

BOLTON DIVISION.—At Gymnasium, Bolton Royal Infirmary, Tuesday, January 8, 8.30 p.m., meeting in conjunction with Bolton Medical Society. B.M.A. Lecture by Professor J. McMichael: "The Management of Hypertensive Disease."

CROYDON DIVISION.—At Croydon General Hospital, Tuesday, January 8, 8.30 p.m., general meeting. B.M.A. Lecture by Dr. Keith Simpson: "Crime Reconstruction" (illustrated).

GUILDFORD DIVISION.—At Royal Surrey County Hospital, Guildford, Thursday, January 10, 8.30 p.m., lecture by Mr. R. Rowden Foote: "Varicose Veins and Ulcers."

HENDON DIVISION.—At Hendon Hall Hotel, London, N.W., Tuesday, January 8, 8.45 p.m., Mr. D. H. Patey: "Chronic Mastitis—a Non-existent Disease."

MID-HERTS DIVISION.—At Cell Barnes Colony Cinema Hall, Friday, January 11, 8.30 p.m., film demonstration and commentary by Mr. D. J. MacRae: (1) "Normal Labour"; (2) "Forceps Delivery"; (3) "Replacement Transfusion."

SOUTH-EAST ESSEX DIVISION.—At Southend General Hospital, Friday, January 4, 8.30 p.m., address by Dr. Walter Hedgcock, Assistant Secretary, B.M.A.: "Current Medical Affairs."

TUNBRIDGE WELLS DIVISION.—At Kent and Sussex Hospital, Tunbridge Wells, Wednesday, January 9, 8.30 p.m., B.M.A. Lecture by Dr. R. A. Trevethick: "First Aid," with coloured film.

Prevention of Dressing Trauma

Jelonet is a dressing for all wounds—its non-adherent properties protect the delicate epithelium and prevent dressing trauma, enabling healing to continue undisturbed. It is used extensively in the treatment of burns and as a dressing following skin-grafting operations. It is non-toxic and compatible with Penicillin and all other antibiotics, and may be used as a means of drainage, or as a packing for deep granulating wounds. It may also be used as an adjuvant in the treatment of varicose ulcers by compression bandaging, and as a means of protecting the skin from irritating discharges. Jelonet may be prescribed by name under the N.H.S. (Form E.C.10) in the following sizes:— single pieces in envelopes, tins containing

5, 10 or 36 pieces, each piece $3\frac{3}{4}$ " x $3\frac{3}{4}$ ".

A special size tin containing a strip 8 yards long by $3\frac{3}{4}$ " wide, folded zig-zag, is available for use in Hospitals and Surgeries. *Formula:— Balsam of Peru B.P. 12.5 grammes ; Yellow Soft Paraffin B.P. 1000 grammes. Sterile — ready for immediate use.*

PARAFFIN GAUZE DRESSING, B.P.C.

Made in England by T. J. SMITH & NEPHEW LIMITED, HULL

Confirms its Success

AS THE LAST WORD IN GERMICIDAL SOAPS

Cidal contains Hexachlorophene, a proved and tested germicide which has the valuable property of being retained on the skin. Because of this content, Cidal penetrates inside the deep folds and pores of the skin attacking resident bacteria. The thin film of Hexachlorophene which remains on the skin, affords effective protection at all times.

FOR PERSONAL USE IN
SURGERIES, HOSPITALS.
SCHOOLS & HOMES.
INVALUABLE WHERE
PEOPLE GATHER IN FACTORIES,
OFFICES, HOTELS ETC.

Guaranteed to contain 2% Hexachlorophene

'SULPHAMEZATHINE'

SULPHADIMIDINE B.P.

TRADE MARK

'Sulphamezathine' has a wide range of antibacterial action, and can be used wherever a sulphonamide is indicated. Toxicity is exceptionally low, and nausea, vomiting and other

common reactions are rarely encountered. Renal complications do not occur. 'Sulphamezathine' is considered by many to be the drug of choice for children and elderly patients.

Available in the form of tablets (0.5 gm.); lozenges; oral suspension; powder; and as the sodium salt in sterile solution for parenteral administration.

'He had a very good night, Doctor'

Doctors know there are very good reasons why Bourn-vita is so successful in inducing deep and restful sleep. Malt, cocoa, milk, sugar and eggs these ingredients help the body to relax and to gain new reserves of energy. Many doctors themselves round off a long day with a cup of Bourn-vita.

**A FUNDAMENTAL ADVANCE
IN SENNA THERAPY**

Senokot

CHOCOLATE LAXATIVE GRANULES

For the first time a standardised preparation of senna has been evolved which retains the full laxative activity of the pod. (J. Pharm. Pharmacol., 1950, 2, 813.)

Thus a new field of usefulness has been opened up for one of the safest and most physiological of laxatives.

SENOKOT is in granule form; it contains cocoa, malt and sugar, has a delicious taste and is very economical.

SENOKOT is tested chemically and biologically and is completely dependable.

SENOKOT is not advertised to the public and may be prescribed on E.C.10 forms.

Supplied in 2 oz. tins and

Faultless Reliability

THE GILLIES MARK III

ANÆSTHESIA APPARATUS

After extensive clinical trials, here is the latest Gillies equipment—compact as ever and readily adaptable to all conditions and all types of gas cylinder.

The Gillies III combines three different circuits in one. It provides for circle-type closed circuit anaesthesia, continuous flow, and atmospheric air with the volatile agents. As with the Boyles Apparatus a Waters Absorber (not included) may be used for "to and fro" closed circuit administration. Incorporating a carbon dioxide absorber the Gillies Mark III is in fact the smallest complete apparatus that combines all these functions.

In hospitals it is equally convenient on a stand or a table; for Service use it will fit in with emergency arrangements. Full details will gladly be supplied on request.

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held, £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

vacant February 6, 1952, for period of five to six months. Salary £400 to £450 per annum, less £100 board residence. Recognized resident anaesthetic post for purpose of taking the D.A. Applications, stating age, nationality, qualifications (with dates), present post, with copies of three recent testimonials, to Administrative Officer. (5363)

BLOOD TRANSFUSION**LEEDS REGIONAL HOSPITAL BOARD**

Applications are invited from suitably qualified practitioners for the whole-time appointment of

**DEPUTY BLOOD TRANSFUSION OFFICER
(S.H.M.O. scale) of the Blood Transfusion Service
in the Leeds Region**

The person appointed will be required to act as Deputy to the Regional Blood Transfusion Officer and opportunities will be given for original work and research of an academic nature. Applicants must have been qualified at least six years and some previous experience in clinical pathology would be desirable. The headquarters of the service is at the Regional Blood Transfusion Centre, Bridge Path, York Road, Seacroft, Leeds. Applications, stating age, qualifications and details of experience, together with the names of three referees, should be forwarded to the Secretary to the Board, Park Parade, Harrogate, not later than Feb. 2. (5294)

SHEFFIELD REGIONAL HOSPITAL BOARD

Applications are invited for the appointment of **WHOLE-TIME ASSISTANT MEDICAL OFFICER
(J.H.M.O. Grade)**

at the Regional Blood Transfusion Centre, Northfield Road, Sheffield. Applicants should have had previous clinical experience. The appointment affords scope in all aspects of blood transfusion work and serology, including research. Applications, stating present appointment, date of birth, qualifications, and experience, and the names of three referees, should be sent to the Secretary, Regional Hospital Board, Fulwood House, Old Fulwood Road, Sheffield, 10, not later than February 2, 1952. Applicants may visit the Blood Transfusion Centre by arrangement with the Director. (5272)

LEEDS REGIONAL HOSPITAL BOARD

Applications are invited for the whole time appointment of

SENIOR HOUSE OFFICER

in the Blood Transfusion Service for the Leeds Region

The person appointed would be required to have one year's experience in house appointments and would be given opportunities to obtain experience in all branches of blood transfusion technique. Previous experience with a regional blood transfusion service is not essential. The headquarters of the service is at the Regional Blood Transfusion Centre, Bridge Path, York Road, Leeds. Applications, stating age, qualifications and details of experience, together with the names of three referees, should be forwarded to the Secretary to the Board, Park Parade, Harrogate, not later than Feb. 2. (5295)

CARDIOLOGY**NATIONAL HEART HOSPITAL**

Westmoreland Street, London, W.1
(With which is associated the Institute of Cardiology)

REGISTRAR

A vacancy for this post will occur as from February 1, 1952. Applicants should have been fully trained in general medicine and should possess a higher medical qualification. The selected candidate will be trained for from one to two years in all aspects of cardiology and should be then ready for a consultant post. Applications, with copies of three recent testimonials, should be sent to me not later than Monday, January 21, 1952.—Robert G. E. Whitney, Secretary to the Board of Governors. (5560)

IMPORTANT: All intending applicants should read the revised NOTICE at the top of page 23

PUBLIC HEALTH

(See Important Notice page 25)

BOLTON, COUNTY BOROUGH OF

Three vacancies exist for

ASSISTANT MEDICAL OFFICERS OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICERS OF HEALTH

and applications are invited from suitably qualified registered medical practitioners for such vacancies. The duties will be mainly in connection with the Maternity and Child Welfare Service and the School Health Service, but the persons appointed will be expected to carry out such duties as may be allotted to them by the Medical Officer of Health. The possession of a D.P.H. or a D.C.H. is desirable, but not essential. The salary will be on the appropriate step of the scale, £850 rising by annual increments of £50 to £1,150 per annum, according to experience and qualifications. The appointments will be subject to the provisions of the Local Government Superannuation Acts, and the successful candidates will be required to pass a medical examination. Appointments will be terminable by one month's notice on either side. There are no forms of application, but further particulars can be obtained from the Medical Officer of Health, Civic Centre, Bolton. Applications, giving full particulars of age, qualifications, and experience, and the names and addresses of three referees, should be forwarded to the undersigned not later than January 24, 1952.—Philip S. Rennison, Town Clerk, Town Hall, Bolton. (5521)

STOCKTON-ON-TEES, BOROUGH OF

Applications are invited from duly qualified medical practitioners for the position of
ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER
The salary will be at the rate of £850 per annum, rising by annual increments of £50 to £1,150 per annum. The duties of the appointment will be principally of a clinical nature and will concern the school health service and the general work of the department. Preference will be given to candidates who hold a Diploma in Public Health or a Diploma in Child Health. The person appointed will not be allowed to engage in private practice and the appointment will be subject to two months' notice. Applications, giving particulars of age, qualifications, experience and present and previous appointments, together with the names of two persons to whom reference may be made, endorsed "Assistant Medical Officer of Health," must be received by the undersigned not later than January 20, 1952.—John B. Haworth, Town Clerk, Barclays Bank Chambers, Stockton-on-Tees. (5572)

LIVERPOOL, CITY OF—PORT HEALTH AUTHORITY**ASSISTANT PORT MEDICAL OFFICER**

Applications are invited for the above appointment. Salary £850 by £50 to £1,150 per annum. The duties will be in connection with the tidal inspection of ships; the medical inspection of aliens; and such other duties as may from time to time be assigned to him by the Medical Officer of Health. Possession of a Diploma in Public Health is desirable. Application forms obtainable from the Medical Officer of Health, Gordon House, Belmont Grove, Liverpool, 6, should be returned to him by January 14, 1952. The appointment is superannuable and subject to the Standing Orders of the City Council. Canvassing disqualifies.—Thomas Alker, Town Clerk and Clerk to the Port Health Authority, Municipal Buildings, Liverpool, 2. (JA.2789) (5522)

NORTHUMBERLAND COUNTY COUNCIL
School Health Service

Applications are invited from registered medical practitioners for the post of

ASSISTANT SCHOOL MEDICAL OFFICER
(Male or female)

Preference will be given to candidates who have experience in the diseases of children, and to those who have been approved by the Minister of Education for the purpose of the ascertainment of educationally subnormal pupils. The salary will be at the rate of £850 per annum, rising by annual increments of £50 to a maximum of £1,150 per annum. Previous experience may be taken into consideration in determining the commencing salary. Traveling expenses and subsistence allowances, in accordance with the Council's scale, will be paid. The appointment is subject to the provisions of the Local Government Superannuation Act, 1937, as amended by the National Health Service (Superannuation) Regulations, and the successful candidate will be required to pass a medical examination. Forms of application, which may be obtained from Dr. J. B. Tilley, School Medical Officer, County Hall, Newcastle-upon-Tyne, 1, should be returned not later than January 26, 1952.—E. P. Harvey, Clerk of the Council, County Hall, Newcastle-upon-Tyne, 1. (5402)

SOUTHAMPTON, COUNTY BOROUGH OF
Health Department

ASSISTANT MEDICAL OFFICER OF HEALTH
Applications are invited from registered medical practitioners for the above whole-time permanent post. The duties will be mainly in connection with port health work, but the person appointed will be expected to carry out such duties in connection with the Maternity and Child Welfare Service and the School Health Service as may be allotted by the Medical Officer of Health. Salary £850 per annum, rising by annual increments of £50 to a maximum of £1,150 per annum. The person appointed will be expected to pass a medical examination and to contribute to the Corporation's Superannuation Fund. Further particulars can be obtained from the Medical Officer of Health, Health Department, Civic Centre, Southampton, to whom forms of application should be returned not later than fourteen days after the appearance of this advertisement. Canvassing will disqualify. (5269)

SWINDON, BOROUGH OF
DEPUTY MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER

Applications are invited from duly qualified medical practitioners holding a Diploma in Public Health or similar qualification for the appointment of Deputy to the Medical Officer of Health and Borough School Medical Officer who is also Area Medical Officer under the Wiltshire County Council. The salary and conditions of service will be in accordance with the recent award of the Industrial Court. The present salary is at the rate of £1,034 per annum, rising by four increments of £50 to a maximum of £1,234 per annum. Assistance will be given in the provision of housing accommodation if required. Forms of application and further particulars of the post may be obtained from the undersigned with whom applications should be lodged not later than Saturday, January 19, 1952.—D. Murray John, Town Clerk, Civic Offices, Swindon. (5256)

WORCESTERSHIRE COUNTY COUNCIL
ASSISTANT COUNTY MEDICAL OFFICER WITH ADDITIONAL PUBLIC HEALTH DUTIES

Applications are invited from registered medical practitioners (men or women) for the above whole-time post. The duties will chiefly concern school health and child welfare services. The possession of the D.C.H. or the D.P.H. and experience in connexion with infectious diseases will be of advantage. The salary and conditions of service will be in accordance with the recent award of the Industrial Court, i.e. £850 per annum, rising by annual increments of £50 to £1,150. Past experience will be considered in fixing the starting point within this scale. The successful candidate must own and drive a car. The holder of this appointment (now vacant) also acted as occasional Deputy at the Hayley Green Isolation Hospital and to the Medical Officer of Health for the boroughs of Halesowen and Stourbridge, for which additional payment is made. The appointed officer will be

considered for all or any of these additional appointments. The post is superannuable, subject to medical examination and determinable by three months' notice. Applications, on forms to be obtained from the County Medical Officer, County Buildings, Worcester, should be returned to him by January 12, 1952.—W. R. Scurfield, Clerk of the County Council. (4921)

GOVERNMENTAL**TREASURY MEDICAL SERVICE**

Applications are invited from medical practitioners, practising in the districts detailed below, for appointment in a part-time and mainly advisory capacity as

LOCAL TREASURY MEDICAL OFFICER

for each of the places or groups of places shown. The town shown in brackets after the place-names indicates the Head Post Office Area in which the place, or group of places, is situated. Successful applicants will be required to examine and report on the condition of certain Government Officers, teachers, candidates for appointment, etc., who may be referred to them from time to time; and to attend when summoned to an emergency case of accident or sudden illness occurring in a Government office in the neighbourhood. Fees for this work, and mileage allowance where necessary, will be paid on a scale agreed with the British Medical Association. Intending applicants should write, within fourteen days, to Treasury Medical Adviser, Treasury Chambers, Whitehall, S.W.1, for a form on which application may be made. Applicants should be not more than 60 years of age.

The places for which applications are invited are as follows:

England and Wales

Honiton (Exeter).
Beckenham (Bromley).
Horwich (Bolton).
Burford (Oxford).

Scotland

Ardgay, Bonar Bridge, Rosehall (Lairg).
Forres, Brodie, Dallas, Dunphail and Glenferness (Elgin).
Llinitgow (Bathgate). (5556)

SERVICES**ROYAL NAVAL MEDICAL SERVICE**

Candidates are invited for service as
MEDICAL OFFICERS

in the Royal Navy—preferably below 28 years. They must be British subjects whose parents are British subjects, and be medically fit. No examination will be held but an interview will be required. Initial entry will be for four years' short service, after which gratuity of £600 (tax free) is payable, but permanent commissions are available for selected short service officers. Officers entered on or after January 1, 1951, will be eligible to be considered for antedates of seniority up to two years for service in recognized civil hospitals, etc. For full details apply Medical Director-General, Admiralty, S.W.1.

INDUSTRIAL APPOINTMENTS

AN IMPORTANT PHARMACEUTICAL MANUFACTURER in the North-West of England wishes to appoint a Consultant Physician as full-time medical adviser. His duties would include the organization and supervision of clinical trials of new and established products, and co-operation with the company's technical information department and other departments in their function of furthering the use of the company's therapeutic products. In addition to the academic qualifications and professional experience for consultant status, some experience of editorial work would be desirable, together with an appreciation of the place of pharmaceutical manufacturers in the progress of medical science. A pharmaceutical qualification would be an added advantage. Applicants should hold some honorary appointments and should be prepared to continue such of these as may facilitate their work. Applicants should be prepared to reside in the Manchester/Liverpool area, but consideration would be given to those wishing to continue living in other areas where they have established contacts. The salary offered will conform to the scale approved to be paid to consultants under the National Health Service.—Applications should be addressed to the Managing Director, Box 2005, B.M.J.

OVERSEAS**BRITISH GUIANA**

Medical Officer, qualified in tropical medicine, general medicine and surgery, required by U.S. industrial company in British Guiana. Laboratory, field hospital, and general practice. Regular leave, furnished living quarters at nominal cost, three-year contract. Starting salary £1,800 annually.—Write, stating particulars, to Box 2004, B.M.J.

Overseas—contd.

ONTARIO, Canada
PHYSICIAN

Required for junior position in private psychiatric hospital. Annual salary £1,500 or more depending on qualifications and experience. Living quarters and full maintenance provided at reasonable cost. Apply by air mail to Medical Superintendent, Homewood Sanitarium, Guelph, Ontario, Canada. (5529)

ALBANY HOSPITAL, Albany, N.Y.

Internships and residencies available in Albany Hospital, Albany, New York, 750-bed general hospital, directly associated with Albany Medical College. House officers receive appointments in medical school. Salaries range from a minimum of \$300 a year for interns to \$1,400 a year for residents. Details on request. (9695)

ALBANY HOSPITAL, Albany, N.Y.

Residency in tuberculosis available at Albany Hospital, Albany, New York, associated with Albany Medical College, beginning July 1, 1952, for a period of twelve months. Salary ranges from \$1,800 to \$2,400. (9920)

ALBANY HOSPITAL, Albany, N.Y.

Approved E.N.T. Residency available July 1, 1952. Affiliated with Albany Medical College, Albany, New York. Salary \$1,200. (3942)

NEW ROCHELLE HOSPITAL

New Rochelle, New York, U.S.A.
(360-bed general community hospital)

Approved by American College of Surgeons, American Medical Association for Internship and Residency training. Only graduates from approved university schools accepted. Interns, \$100 per month, plus full maintenance. Vacancies on or about July 1, 1952. (5427)

ST. VINCENT'S HOSPITAL

Staten Island, New York City, N.Y.

Opening for three Rotating Internships starting July 1, 1952, and four Rotating Internships starting October 1, 1952. Opening for Medical Resident, and Paediatric starting July 1, 1952. Stipend \$100 per month for interns, \$150 for residents, plus full maintenance. Excellent educational programme. All appointments are for one year. Address applications, Dr. George W. McCormick, Chairman, St. Vincent's Hospital, Staten Island, New York City, N.Y. (5528)

BRITISH EMPIRE CANCER CAMPAIGN invites applications from British subjects for Exchange Fellowships in Cancer Research offered by the National Cancer Institute of Canada and the American Cancer Society. Completed applications must be received by February 29, 1952. Fellowships are of one year's tenure at a stipend of \$4,000. Travelling expenses to and from centre of work will be borne by the Campaign. For further particulars and application forms apply to the Secretary-General, British Empire Cancer Campaign, 11, Grosvenor Crescent, Hyde Park Corner, London, S.W.1. (5405)

NORTHLAND HOSPITAL BOARD

Whangarei, New Zealand

JUNIOR REGISTRAR

Kaipara Hospital, Te Kopuru

Applications are invited from those qualified for the above position, which would be particularly attractive to a second year man. There is a little maternity work undertaken, with plenty of opportunity for surgery and medicine at the General Hospital, which averages 32 occupied beds daily. Accommodation: A partly furnished house is available for the successful applicant. Salary scale: £661 to £718 (one increment of £50). Applications should be addressed to the undersigned.—A. G. Wilson, Secretary, Northland Hospital Board, P.O. Box 403, Whangarei, New Zealand. (5526)

PRETORIA HOSPITAL—UNIVERSITY OF PRETORIA, South Africa
CHIEF BACTERIOLOGIST
PRETORIA HOSPITAL, AND PROFESSOR IN BACTERIOLOGY, MEDICAL FACULTY

Applications are invited from suitably qualified Bacteriologists for the above-named full-time post in the joint service of the Pretoria Hospital and the University of Pretoria on the following conditions: Salary £2,500 per annum, plus ruling cost-of-living. Married rate £256 per annum, single rate £80 per annum. Applicants must be registrable with the South African Medical and Dental Council. Applications should be addressed to the Medical Superintendent, Pretoria Hospital, Pretoria, and should contain full particulars with regard to age, professional, academic and language qualifications, previous experience, teaching experience, if any, and when able to assume duties, should application be successful. Should the successful applicant not be proficient in Afrikaans and English he shall have to undertake to become proficient in both languages within a reasonable time. Closing date for applications February 20, 1952. (5557)

WAIKATO HOSPITAL BOARD

Applications, closing on February 25, 1952, are invited from qualified medical practitioners for the full-time position of

ANAESTHETIST

at the Waikato Hospital, Hamilton, New Zealand. Salary, according to qualifications and experience, as follows: **Senior Specialist Grading:** Minimum £1,500. Maximum £1,750 per annum. Annual increments £50, plus cost-of-living bonus of £160 per annum. **Non-resident, Junior Specialist Grading:** Minimum £1,100, maximum £1,400 per annum. Annual increments £50, plus cost-of-living bonus of £160 per annum. Non-resident. Conditions of appointment obtainable from the High Commissioner for New Zealand, 415, Strand, London, W.C.2. Transport expenses of successful applicant and of wife and dependent children, if resident in United Kingdom at the time of appointment, payable as per conditions of appointment. Applications, with copies of recent testimonials, stating age, qualifications, and experience, to be addressed to the undersigned.—A. C. Burgess, Secretary, P.O. Box 14, Hamilton, New Zealand. (5215)

HIS MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom, with one or more years' experience after qualification, are required for appointment as

MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH

for general medical and health duties. A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan medical service. Appointment is available (a) on probation for permanent establishment, (b) on employment from the National Health Service, and (c) on short term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g. F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malayan salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their Colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e. those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No 27215/242/51). (5187)

EIRE

GALWAY COUNTY COUNCIL

Applications are invited for the following posts in Galway Central Hospital as from Feb. 1, 1952:

SENIOR RESIDENT SURGICAL OFFICER for a period of six months in the first instance. Remuneration at the rate of £200 per annum, with rations, apartments, fuel, light, laundry, and attendance, together with temporary bonus of £41 18s. per annum. Applicants must not be less than 24 years of age on January 1, 1952, and must have had twelve months' experience in a hospital as a Resident Medical Officer, six months of which must have been gained in the post of Resident House Surgeon in a general hospital.
FOUR JUNIOR RESIDENT HOUSE SURGEONS (including one Obstetrical and one Casualty Officer) for a period of six months. Remuneration at the rate of £150 per annum with rations, etc., plus temporary bonus of £41 18s. per annum. Applicants must not be less than 23 years of age on January 1, 1952.

Applications, stating date of birth, together with certificate of registration, testimonials, and certificates of experience, should be lodged with the Secretary, Galway County Council, County Buildings, Galway, immediately. (5558)

UNIVERSITY APPOINTMENTS

THE BRITISH EMPIRE CANCER CAMPAIGN

invites applications for Fellowships in Cancer Research. These Fellowships will be intermediate between the Campaign's existing Senior and Junior Fellowships, and will normally be tenable for five years at a salary of £1,500 by £100 to £1,900 per annum. Fellowships are full-time and will carry superannuation. Fellowships are open to any person of British nationality who, at the date of election, has taken a degree in any faculty in any university in the British Empire approved by the campaign, or who, if a female, has passed an examination which would have entitled her, if a male, to take any such degree. The possession by a Fellow at the date of election of a medical diploma registrable in the United Kingdom will be accepted as a qualification for a Fellowship in lieu of a degree. Elections will take place in June, 1952, and work, if possible, should be begun before the end of the year. Fellows must carry on their research initially in Great Britain or in Northern Ireland, and only at the place at which they are authorized by the Campaign to work. The fares of successful candidates from overseas will be paid by the Campaign. The closing date for the receipt of applications is May 1, 1952. For further particulars and application forms apply to the Secretary-General, British Empire Cancer Campaign, 11, Grosvenor Crescent, Hyde Park Corner, London, S.W.1. (5404)

UNIVERSITY OF ABERDEEN

Applications are invited for the post of
LECTURER IN MATERIA MEDICA

Candidates should have special experience in experimental pharmacology. Salary on medical scale £1,000 by £100 to £1,300 or £1,400 by £100 to £2,000 or on non-medical scale £800 by £50 to £1,100 or £1,100 by £50 to £1,300, scale and placing therein according to qualifications and experience, with F.S.S.U. and children's allowances. The University will pay a proportion of furniture removal expenses. Applications to be lodged with the Secretary (from whom forms of application and conditions of appointment may be obtained) not later than January 31, 1952.—H. J. Butchart, Secretary, The University, Aberdeen. (5183)

UNIVERSITY OF ABERDEEN

Applications are invited for a
LECTURER IN CLINICAL CHEMISTRY

Applicants must have a medical degree and preferably have special qualifications in chemistry and physiology. Salary £600 by £100 to £900 or £1,000 by £100 to £1,300, scale and placing therein according to qualifications and experience, with F.S.S.U. and children's allowance. The University will pay a proportion of furniture removal expenses. Applications should reach the Secretary to the University (from whom forms of application and conditions of appointment may be obtained) not later than January 31, 1952.—H. J. Butchart, Secretary, The University, Aberdeen. (5184)

UNIVERSITY OF LEEDS
School of Medicine

Applications are invited from registered medical practitioners for the post of
either LECTURER or ASSISTANT LECTURER IN PATHOLOGY

Salary scale for Lecturer £1,000 by £100 to £1,500 a year. Salary scale for Assistant Lecturer £600 by £100 to £800 a year. The initial salary may be fixed above the minimum of the scale according to the experience and qualifications of the candidate selected. Applications (three copies) should reach the Registrar, The University, Leeds, 2 (from whom further particulars may be obtained), not later than January 21, 1952. (5525)

The fee for the course of ten lectures is £3 3s. for a single lecture 7s. 6d. Applications for tickets of admission, accompanied by a remittance, should be sent to The Secretary, Institute of Child Health, The Hospital for Sick Children, Great Ormond Street, London, W.C.1. Early application is advisable as the number of tickets is limited. (5135)

SITUATIONS VACANT

British Postgraduate Medical Federation (University of London). Science Graduate, with experience in clinical biochemistry, to work on metabolic studies at the Institute of Orthopaedics, Royal National Orthopaedic Hospital, Stanmore, Middlesex. Salary £450 by £50 to £550.—Apply within fourteen days to the Secretary, Institute of Orthopaedics, 234, Great Portland Street, London, W.1.

King Edward Memorial Hospital, Ealing, South-West Middlesex Hospital Management Committee.—Applications are invited for the post of **Histological Technician**, vacant February 4, 1952. Candidates should be Associates of the Institute of Medical Laboratory Technology holding a Diploma in Histology, but consideration will be given to candidates holding the Intermediate diploma. Salary and conditions in accordance with Whitley Council scales. Applications in writing, stating age, experience, and names of two referees, to the Pathologist in Charge at the hospital.

SITUATIONS WANTED

Experienced Clinical Psychologist wishes to obtain whole- or part-time appointment in hospital or clinic. References can be given.—Box 2010, B.M.J.

**RECEPTIONISTS, SECRETARIES,
TYPISTS, ETC.**

AVAILABLE

Experienced secretary (driver), used medical phraseology, seeks post, West End London (consider residential). Medical testimonials.—Box 2009, B.M.J.

Lady, experienced (25), Jewish, desires resident post, nannie, secretarial, dispensing or combined.—Box 2033, B.M.J.

Lady seeks part-time receptionist post to doctor or dentist, West End.—Box 2034, B.M.J.

Single lady, 30, desires Part-time Post with doctor. Experienced bookkeeper, French, typing.—Box 2024, B.M.J.

Applicants requiring testimonials, theses, copies or duplicated, should communicate with Manton Secretarial Service, Ltd., 98, Victoria Street, S.W.1 (Victoria 0141), who are specialists.

Thoroughly trained Medical Secretarial staff may be engaged through Brook Street Bureau, Ltd., 59, Brook Street, W.1, Gro. 6666, and 2, George Street, Croydon. Phone 3363.

DOMESTIC SERVICE

AVAILABLE

Cook-generals, married couples, etc., obtainable from abroad.—Isobel Jay, Limited, 98, Western Road, Hove, Sussex. Tel.: 37216.

HOUSEKEEPERS

VACANT

Gentlewoman (under 45) needed early January. Share with another running house for two women radiologists, South Coast town. Catering, shopping, housework, some cooking. Resident maid. Interview, references. State age and all particulars. House unsuitable for children.—Box 2003, B.M.J.

HOUSEKEEPERS

AVAILABLE

Vicar's widow, experienced driver, own car, travelled, desires post hostess-housekeeper chauffeur to country doctor. Dog allowed. Interview.—Box 2035, B.M.J.

ACCOMMODATION

AVAILABLE

Norfolk Hall, 25, Norfolk Square, W.2. Quiet, well-appointed accommodation. Car parking facilities, from 4½ guineas. Dinner, bed and breakfast. Resident Proprietor. Tel.: Pad. 8596.

CONSULTING ROOMS, ETC.

AVAILABLE

Consulting Room to Let, ground floor, Devonshire Place, W.1, £330 per annum inclusive of rates, hot water, central heating, waiting-room, services of receptionist. Doctors or dentists only.—Apply Alfred Neale & Co., 118/119, Chapside, E.C.2. MONarch 0535.

For Consulting Rooms and Houses in Harley Street, etc., apply C. E. Bedford & Co., Ltd., 10, Wigmore Street, W.1. Langham 3927.

To Doctors prescribing a bland diet

IT HAS BEEN BROUGHT to our notice by a medical practitioner that adults needing bland food have their requirements met by the varied and appetising diet of meats, vegetables and sweets that we prepare, primarily for babies, in the form of our Strained Foods.

These foods, of course, contain no pepper or other spice. All *coarse* fibres are removed by sieving, but the foods retain enough bulk material to help the bowel function properly.

Cooking in the Heinz kitchens is done by

more scientific methods of conserving than are practicable at home, and the vegetables are grown near the kitchens to ensure maximum retention of nutrients.

The *variety* of Heinz Strained Foods available helps to prevent that failure of appetite which sometimes affects adults on less interesting types of bland food.

The convenience of these ready-prepared foods, and their economy, are other points in their favour. All sixteen varieties sell at 7d.

Strained Tomato Soup

Ripe tomatoes cooked with wheat germ, whey powder, riceflour, sugar and sieved to smoothness.

Strained Vegetable Soup

A delicious blend of fresh vegetables strained to a fine purée.

Strained Chicken Broth with Vegetables & Cereal

Young chicken with peas, wheat germ, cereal, and the chicken broth.

Strained Beef Broth with Beef and Barley
Broth made from lean beef with added beef meat, finely sieved, and barley.

Strained Bone and Vegetable Broth
A blend of lean beef and fresh vegetables with glucose, added to a bone broth.

Strained Beef and Liver Soup

Tender lamb's liver blended with ground lean beef, fresh vegetables, tomato purée and cereal, thinned with beef broth.

Strained Peas

Young, tender peas, cooked and sieved to a smooth purée.

Strained Green Beans

Crisp French beans cooked and with all coarse fibre removed.

Strained Beets

Selected young beets cooked and sieved.

Strained Spinach

The best dark green, freshly gathered spinach, carefully washed and cooked to retain maximum nutrient value, and sieved to a fine purée.

Strained Carrots

Sweet, juicy carrots cooked to tenderness and sieved.

Strained Prunes

A smooth prune purée with lemon juice.

Strained Apples

A smooth, sweet purée of blended cooked apples.

Strained Apple, Prune and Custard

A blend of apple and prune with milk, eggs, cornflour, riceflour and sugar.

Strained Custard Pudding

Eggs, milk, sugar, riceflour and cornflour make this nourishing pudding—it is smooth and delicious.

Strained Plums with Semolina

Ripe plums, cooked and blended with semolina and sugar.

THE PHYSIOLOGY AND RELIEF OF TRAUMATIC ARTERIAL SPASM*

BY

J. B. KINMONTH, M.S., F.R.C.S.

Assistant Director, Surgical Professorial Unit, St. Bartholomew's Hospital, London

When these lectures were founded by Edward Arris in 1646 the lecturers were called the "Readers of the Muscular Lecture." Such a title would be appropriate to-day because the studies to be described deal largely with muscle. It is not, however, the striped muscles described in the old "Public Anatomies" but the smooth muscle of blood vessels which will be considered here.

The clinical aspects of traumatic arterial spasm must be briefly discussed before considering the physiology of its production and relief. The larger vessels of the limbs such as the brachial or femoral arteries are those usually affected, and the spasm follows injury near by, often a fracture, dislocation, or gunshot wound. Sometimes the cause may be dissection of an artery during a surgical operation such as arteriography or vein ligation. A length of vessel may remain in spasm for hours or even days, and ischaemic contracture of muscle or gangrene of the limb may result. This contractile power of major arteries has been known for many years. Hunter, who with Pott gave the first Arris and Gale lectures under the Company of Surgeons, was aware of it. He described many instances in man and animals, and knew that it was part of the natural mechanism for suppressing bleeding (Hunter's Works, 1835). When, however, an artery is injured without being opened this protective mechanism is unnecessary because there is no bleeding to stop, and harmful because the circulation to the part is arrested. More recently the clinical side of the problem has been well described by Cohen (1940) and Griffiths (1940) in Hunterian Lectures, but until the work of Barnes and Trueta in 1942 there had been few investigations of the cause or cure of arterial spasm under experimental conditions. This is unfortunate, because the difficulty of obtaining standard conditions has always made it hard to judge the effects of treatment in clinical practice. The artery affected, the type of injury, and the time that has elapsed before the treatment starts may all vary from one patient to another. The present studies were chiefly made in the laboratory. They will be considered in two parts: (1) the causes of arterial spasm or other alterations in the size of large arteries; and (2) the cure of arterial spasm.

Causes of Spasm or Other Alterations in Size of Large Arteries

The concept of a nervous reflex arc has been widely held. Barnes and Trueta (1942) and Trueta and his

colleagues (1947) described experiments in rabbits in which a tourniquet applied to the thigh for several hours produced shrinking of the femoral artery on the other side. These findings were taken as the basis for studies made at Harvard in 1948. The details of some of these earlier experiments have already been published (Kinmonth, Simeone, and Perlow, 1949), so that it will now only be necessary to outline them in order to understand what follows. The tourniquet experiments of Trueta and his co-workers were repeated, using a technique which allowed continuous observation and measurement of the arterial diameter. The arterial tree on the side opposite to the tourniquet shrank in the way in which they had described. This shrinking occurred gradually and coincided with a slow fall in blood pressure in a way suggesting a close relation between the two. Tourniquet experiments were then done on rabbits in which bilateral lumbar sympathectomy or denervation of the hind limb had been performed. The same shrinking of the arterial tree on the opposite side took place except in animals in which the blood pressure remained level. This suggested that a gradual fall in blood pressure might cause a parallel shrinking of the femoral artery independently of the presence of intact nerve pathways.

The next step was to see whether alterations in the blood pressure due to other causes might change the arterial diameter. Different methods of altering the blood pressure were used and the effects on the upper third of the femoral artery recorded. The results are shown in Table I. They refer to findings in the rabbit

TABLE I.—Effect of Blood-pressure Changes on the Femoral Artery

	Blood Pressure	Arterial Diameter
Open ether	↓	↓
Pentobarbitone sodium (i.v.) ..	↓	↓
"Shock" due to tourniquets, haemorrhage, etc.	↓	↓
Priscol (i.v.) (cat)	↓	↓
Afferent nerve stimulation	↑	↑
Adrenaline (i.v.)	↑	↑
Tracheal obstruction	↑	↑

except in the case of "priscol," where these experiments were done on the cat. Priscol (tolazoline hydrochloride) is a benzyl-imidazoline compound which dilates the small vessels of the peripheral circulation. It has a depressor effect in the cat, and this makes the femoral artery shrink.

The arterial diameter follows the changes in blood pressure whatever the effect of any particular agent may

*Based upon an Arris and Gale Lecture given at the Royal College of Surgeons on May 29, 1951.

FIG. 1.—Effect of tracheal obstruction on the systemic blood pressure and femoral artery of the rabbit. Anaesthesia with urethane. Arterial diameter measured just below inguinal ligament. Trachea obstructed from second to fifth signals. Time signal (lowest record), 10 seconds.

be upon the peripheral part of the arterial tree. Fig. 1 shows how the femoral arterial diameter changes with the rise in systemic blood pressure when the trachea is temporarily closed. It follows that the blood pressure should always be recorded in experiments on arterial spasm, otherwise changes in arterial size due to alterations in blood pressure may be falsely attributed to efforts to produce or to relieve spasm. The concept of a nervous reflex arc was further examined by tests on its possible efferent components. The femoral artery was chosen for detailed study in the rabbit, and tests were made in three ways. First, the artery was stimulated directly with a faradic current. This had no effect on the upper third near the inguinal ligament, but further down marked contraction resulted. Secondly, the lumbar sympathetic chain was stimulated electrically. This had no effect upon the upper third of the femoral artery although shrinking of the paw recorded by a plethysmograph showed that the stimulus was effective. Lumbar sympathetic stimulation provoked a marked contraction of the more distal part of the femoral artery. The third method of testing for the efferent component of a reflex arc was to give an intravenous injection of adrenaline and record the change in the femoral arterial diameter. Fig. 2 shows the effect of an intravenous injection of adrenaline on the blood pressure and the diameters of the upper and lower parts of the femoral artery observed

FIG. 2.—Effect of adrenaline on the systemic blood pressure of a rabbit and on its femoral artery measured simultaneously 3 mm. and 80 mm. below the inguinal ligament. Urethane anaesthesia. Injection of 1 ml. of 1 in 50,000 adrenaline intravenously at fifth signal (lowest record). Time signal, 30 seconds.

simultaneously with two microscopes. The lower part of the femoral artery was seen to contract, but the upper part actually dilated in phase with the rise in blood pressure. Had there been adrenergic sympathetic motor-nerve endings in the upper one-third of the artery the adrenaline would have been expected to have acted upon them to cause contraction.

These observations were repeated many times with consistent results and recorded in detail elsewhere (Kinmonth and Simeone, 1952). They revealed no evidence of vasoconstrictor nerve supply to the upper third of the femoral artery, and yet this part of the vessel may be readily put into spasm by mechanical trauma, and on microscopical examination is found to contain much smooth muscle in its wall.

A similar state exists in man, although it has not yet been possible to determine in detail the level at which the motor-nerve supply becomes evident. Fig. 3 shows how electric stimulation of the dorsalis pedis artery of a patient during the course of a surgical operation produced a definite contraction.

FIG. 3.—Contraction of a healthy small artery (the dorsalis pedis) in response to direct electric stimulation in a woman aged 27.

Stimulation of larger vessels such as the common femoral artery (Fig. 4) produced no contraction. This particular common femoral exhibited partial traumatic spasm when a needle was introduced later for arteriography.

Dr. F. A. Simeone has tried the effect of a variety of direct electric stimuli on large arteries during the course of surgical operations, but always without causing contraction. I have found the same, and yet these arteries will go into spasm if subjected to mechanical trauma.

Arterial spasm may be produced in the experimental animal by applying mechanical trauma to the artery in different ways. Pinching, longitudinal traction, handling with forceps, or rubbing with gauze may cause it. Sometimes additional trauma may produce a localized fusiform dilatation with spasm at each end similar to that described by Grant (1930) in the main artery of the rabbit's ear. The actual irritability of the vessels and their response to trauma vary. It is difficult to produce spasm a second time after relaxation has occurred, and sometimes an animal is found in which it cannot be produced at all. The causes of these variations in irritability are not clear, and are being studied further.

FIG. 4.—Direct electric stimulation of large arteries, in this case the common femoral of a woman aged 42, causes no contraction, although mechanical stimuli may do so.

That an intact sympathetic nerve supply was unnecessary for the maintenance of arterial spasm was shown by experiments in rabbits in which spasm was produced by deliberate periarterial stripping of the vessel. The arterial wall was cleanly stripped of its adventitia and possible nerve supply, and yet the spasm lasted for one to two hours. In man, also, local arterial spasm can persist for long periods after the sympathetic nerve supply has been removed from vessels by the operation of periarterial stripping.

It was accepted as a working hypothesis that traumatic spasm is due to mechanical stimulation of the vessel wall resulting in a sustained contraction of smooth muscle in the maintenance of which nervous factors do not play a demonstrable part. With this conclusion in mind, methods of relieving traumatic spasm were considered.

Methods of Relieving Arterial Spasm

At least a dozen different methods of relieving arterial spasm have been tried in clinical practice. They have included the intravenous injection of drugs and simple exploration as well as more drastic procedures like periarterial stripping or arteriotomy, and success has been claimed at times for almost all of them, even the most unlikely. The probable reason is that arterial spasm lasts for a variable time after the injury, and spontaneous relaxation may coincide with treatment.

In the laboratory, controlled experiments under standard conditions are possible and provide a more reliable test of the success or failure of therapeutic measures. Most of our experiments on the relief of traumatic spasm have been done on rabbits anaesthetized with urethane or "dial." A continuous record of the systemic blood pressure has been kept throughout with a carotid cannula and mercury manometer to prevent confusion due to possible changes in arterial diameter caused by alterations in blood pressure. The arterial diameter was measured by direct observation with dissecting microscopes fitted with micrometers. The upper third of the femoral artery just below the inguinal ligament was chosen for particular study, and this was put in spasm by deliberately rough dissection and then covered by normal saline solution to prevent drying. The vessel on the opposite limb was dealt with in the same way, and so far as possible at the same time, to provide a control. A series of animals were observed in this way to see how long the untreated spastic arteries

took to relax. Fig. 5 is a typical example of the slow and gradual natural relaxation of the vessels, which was similar on the two sides. The rate of relaxation slowed down after two hours as the animal's condition deteriorated and the blood pressure fell.

A number of drugs were applied to arteries which had been put into spasm in the way described to see if they would relax them. The chief drugs chosen were known to have a direct action on smooth muscles, because the preliminary work had suggested that smooth-muscle contraction was the important factor in the spasm rather than nervous activity.

Direct application was chosen because it was considered that substances circulating in the blood would have little chance of reaching the muscle in the arterial wall. Under clinical and experimental conditions the lumen of the spastic vessel is often totally closed and the vasa vasorum damaged by the injury which caused the spasm. Each drug was tested several times in different animals, and the results shown in the figures are typical examples.

The first substance to be used was papaverine, and Fig. 6 shows the result of applying a 2.5% solution of the sulphate to vessels which had been put in spasm in the usual way. Intravenous injection of papaverine was without effect on the spastic vessels, nor did it have effect on any of the numerous occasions on which it was tried in other animals—a finding in agreement with results in man (Learmonth, 1950, personal communication). The drug relaxed the vessels rapidly when applied direct to them, and they remained relaxed after it was replaced by saline. There was no rise in blood

FIG. 5.—Example of the gradual and symmetrical way in which natural relaxation of traumatic spasm occurs in the femoral artery of a rabbit over a period of about two hours. Urethane anaesthesia.

pressure which could have accounted for the changes. In other animals more dilute solutions, 1% or 1.25%, were also effective when applied direct to spastic arteries.

The effect of caffeine, which is another smooth-muscle-relaxing agent, is shown in Fig. 7. Intravenous injections

were without effect. Local application dilated the spastic vessels, but they contracted again after the caffeine solution was removed. The blood pressure showed some abrupt falls, perhaps due to the irritant effect of the caffeine citrate solution, but there were no peaks which could have caused the swelling of the vessels.

There have been some clinical reports of relief of spasm by irrigation with warm saline. Fig. 8 shows how repeated irrigation of the wound and spastic artery with saline at 50° C. at intervals produced gradual relaxation over a period of an hour. At the end of this time application of papaverine solution to the control artery on the other side caused a greater relaxation in a few minutes.

The relaxing effect of procaine on arterial spasm is shown in Fig. 9. In this animal there was no contraction of the vessels after the procaine was removed, but in others shrinking was observed. The permanence of the effect of procaine varies.

It was suggested to me by Dr. N. E. Freeman (1949, personal communication) that local application of heparin might be of value in relaxing spasm, as it is considered to have some dilating effects on small vessels as well as its effect on blood coagulation. That this might be so was also suggested by the fact that protamine sulphate, an antagonist of heparin, is known to contract arterioles and had been found in some of our experiments to produce a partial contraction of large arteries. A solution of heparin containing 1,000 units per ml. was therefore applied to the spastic femoral artery of a rabbit, but was found to have no effect upon the diameter. Subsequent application of papaverine produced prompt relaxation. In other animals, when its haemorrhagic effect did not obscure vision, heparin also failed to relieve arterial spasm.

Priscol, which relaxes small vessels, was also found to relax large arteries, as Fig. 10 shows, but the artery contracted again after the drug was removed. Similar results were obtained in other animals. Intravenous injections were without effect.

Another drug which was tried was benzodioxane. This is known for its so-called sympatholytic effects and its use in the diagnosis of pheochromocytoma. It produced only partial relaxation, which could be completed by replacing the benzodioxane with papaverine. Inhalations of amyl nitrite were also tried. They produced falls in systemic blood pressure, but did not affect the spastic arteries.

FIG. 6.—Intravenous papaverine, 1.5 mg. per kg., fails to relieve spasm which is subsequently relaxed by direct application of a 2.5% solution of the drug. The vessels remain dilated when the drug is removed. Arteries measured 11 mm. below inguinal ligaments. Rabbits anaesthetized with urethane

FIG. 7.—Rabbit anaesthetized with urethane. Spastic vessels unaffected by intravenous injections of caffeine citrate, 1.5 mg. per kg. Relaxation produced by direct application of 1% caffeine citrate retrogresses when this is replaced by saline. Permanent relaxation by 1% papaverine sulphate. Arteries measured 6 mm. below inguinal ligaments.

Papaverine was the only drug of all those tried which consistently produced relaxation which did not retrogress if the drug was removed. It was used altogether on 31 spastic arteries, all of which it effectively dilated. Procaine and caffeine were the next most successful drugs.

Effect of Papaverine on Wound-healing

The effects of papaverine on living tissues were studied in rabbits before using it in human wounds. The femoral vessels and nerve were exposed, the artery was put in spasm by rough dissection, and the wound was filled with 2.5% papaverine solution. After fifteen minutes the wound was closed, leaving some of the solution inside. A similar operation was done on the opposite side, using saline. The two wounds healed equally, and histological examination, when the animals were killed at intervals of one to eight weeks, showed no difference between the tissues on the two sides. The papaverine solution sometimes turned blood clot in the wound to a brown colour, but this does not appear to have been harmful.

Clinical Application

The results of the many different forms of treatment which have been tried for arterial spasm are reviewed in Table II. The results of conservative operations, such as simple exploration and perhaps bathing the vessel with warm saline or serum, are compared with those of operations in which periarterial stripping or arteriectomy was performed. The cases in which gangrene or muscle contracture followed are classed as failures. These are the results of 59 cases published by various authors in which the diagnosis of traumatic arterial spasm was definite, and in which full details of the end-results were given.

The brachial and femoral were the arteries most often affected. There were most failures in the group in which stripping or arterial excision was done. This difference was particularly marked in the case of the brachial artery. The popliteal artery maintained its sinister reputation, with gangrene in three cases out of seven, even though treated by conservative operation.

Clinical and laboratory experience suggests the following scheme of management:

1. Early exploration of the injured vessel must be performed. It will then

FIG. 8.—Rabbit anaesthetized with urethane. Gradual relaxation of spastic artery by repeated irrigation with hot saline (50° C.), compared with rapid and greater relaxation produced by 1 in 40 papaverine solution. Diameters measured in proximal third of femoral arteries.

FIG. 9.—Rabbit anaesthetized with urethane. Direct application of 4% procaine solution dilates the left femoral artery, which does not constrict when the drug is washed off with saline. Intravenous procaine, 3 mg. per kg. and 6 mg. per kg., does not affect the right femoral artery, which is subsequently dilated by direct application of the drug. Diameters measured 1 mm. below inguinal ligaments.

FIG. 10.—Rabbit anaesthetized with urethane. Spasm in left femoral artery is relieved by direct application of priscol, but recurs after the drug is removed. Point of measurement 7 mm. below inguinal ligament.

be possible to distinguish between true spasm and compression of the artery by bleeding and swelling under skin and fascia. They require different treatment. Neither will respond to systemic injections of drugs which will never reach the vessel wall.

2. If arterial compression is found it is dealt with in the usual way; blood clot is removed and skin and fascia are incised longitudinally until all constriction is removed and the artery is seen to expand and pulsate satisfactorily.

3. If the artery is in spasm it must be exposed in the same way. It is important to see a normal pulsating length of vessel above the spastic segment. If this is not done quite a short length of spasm remaining at the proximal end may prevent relaxed vessel below from filling with blood or dilating.

4. The artery is covered by a warm 2.5% solution of papaverine sulphate and left for a few minutes.

5. Should relaxation not occur within 10 to 15 minutes the wound is loosely closed, leaving a fine polythene tube down to the vessel for instillation of 1% papaverine at intervals until the circulation is restored.

6. It is important to treat shock and to restore a normal blood pressure on general grounds, and because spastic vessels will not dilate if the blood pressure is low.

This regime has been tried in two patients with arterial spasm occurring during operation. In both cases papaverine caused prompt relaxation.

Summary

Arterial contraction due to a supposed nervous reflex arc was explained by shrinkage due to falling systemic blood pressure. The diameter of large arteries changed with alterations in blood pressure produced by different means. Attempts to produce contraction of large arteries by electric stimulation of the efferent components of possible reflex arcs were unsuccessful.

Direct mechanical trauma applied to the vessel wall in various ways produced lasting spasm which could not be relieved by sympathectomy.

Attempts to relieve established traumatic spasm were therefore directed at paralyzing smooth muscle itself rather than sympathetic nerves.

Smooth-muscle-relaxing drugs were successful in relaxing spasm when applied direct to the vessel. Intravenous injections were ineffective.

Papaverine was the most consistently successful in producing permanent relaxation. It was not injurious to living tissues.

I gladly acknowledge my debt to many people who have helped with this work: Dr. F. A. Simeone, with whom much of the fundamental part of the work was done at Harvard; Professor G. Perkins, at St. Thomas's, and Professor Sir James Paterson Ross, at St. Bartholomew's, in whose departments it was continued; Dr. G. Cunningham for his help with the microscopical histology; Mr. G. J. Hadfield, who helped with many of the operations; and Mr. F. Scholefield and Miss D. Gay for technical assistance.

A SIMPLE STANDARD EXERCISE TEST AND ITS USE FOR MEASURING EXERTION DYSPNOEA

BY

P. HUGH-JONES, M.D., M.R.C.P.

With the assistance of A. V. LAMBERT

(From the Medical Research Council Pneumoconiosis Unit,
Llandough Hospital, Cardiff)

In the management and study of patients who have their exercise capacity reduced by heart or lung disease some way of estimating the degree of breathlessness on exertion is often required. Only a rough estimate can be got from the patients' descriptions of their symptoms, which, although helpful in diagnosis, are inadequate for many purposes. An objective and more precise estimate is needed for a reliable judgment of the effects of treatment or for comparing one method of treatment with another, for assessing the patient's capacity for physical work during rehabilitation, for awarding compensation in industrial pulmonary disease, and for many types of survey investigation.

For these purposes various exercise-tolerance tests have been devised. A type of test which is simple, and commonly used, is to get the patient to step up and down from a stool or chair and, at the end of a period of exercise, to assess his response subjectively in terms of "breathlessness," or objectively by counting the respiratory and pulse rates. This sort of test has been criticized by a number of workers (Brittingham and White, 1922; Wahlund, 1948; Renner, 1951). There are two main objections to it, as it is usually done:

1. The amount of exercise is not measured. It depends on the rate and time of stepping and on the height of the stool or chair, and also varies individually with the weight of the patient.
2. The ventilatory cost of the exercise is not measured. This cannot be measured by counting the respiratory rate, because the depth of breathing may not remain constant, while the recovery pulse is variable even in normal subjects and is not well related to ventilation (Cotton *et al.*, 1916; Mann, 1918; Reisinger, 1938; Belayew, 1948; N. P. V. Lundgren, 1951, personal communication); although some observers contend that the pulse rate gives useful information concerning the state of the circulation (Meakins and Gunson, 1916; Master and Oppenheimer, 1929).

A known amount of exercise can be given by a bicycle ergometer or a treadmill, but these machines are usually impracticable for clinical use owing to their complexity and immobility. Thus various modifications of the simple step-test have been suggested in attempts to make it objective and precise. Some of these, in which the subject's maximum effort is sought (Lundgren, 1949; Behnke, 1942) may be useful as efficiency tests in fit subjects but are too distressing for ill patients, while others (Nylin, 1933, 1936; Master, 1935), although they are submaximal tests and are designed to give quantitative results, have other drawbacks. Nylin's test requires a special stairway, and, although Master's test is simple, the results merely show whether a patient's exercise tolerance is "within average figures," the exact response being obtainable only by trial and error in repeat testing. Neither of these tests measures breathlessness.

In this paper, modifications to the step-test are described which allow it to be used for giving a standardized and known amount of exercise without appreciably

impairing its simplicity. The response to it is measured in terms appropriate for the quantitative expression of breathlessness.

Principles of the Test

The exercise is standardized by arranging that every patient does the same amount of mechanical work with approximately the same efficiency. The ventilatory cost of the work is found by measuring the volume of air exhaled per minute for an appropriate time before, during, and after the exercise.

In arranging that each subject does a standard amount of exercise regardless of his weight the test resembles that of exercise with a bicycle ergometer. It differs from a step-test used by Baldwin, Courmand, and Richards (1948) in which the exercise is standard only "in that each subject performs a standard number of steps within one minute of time." It may be asked: Why use standard exercise for all patients when they vary in weight and have to carry that weight about? The answer depends upon what is required of an exercise test. If only a specific function such as a subject's ability to go up steps or to walk at a given rate is to be assessed, then clearly a direct test of this function is to be preferred to a standard test. Standard exercise is useful as a general test in that it is not specific to any particular task. Further, standard exercise is preferable for the assessment of change in ventilatory efficiency over a period of time—for example, in assessing the effects of treating heart failure, or when reassessing a patient for compensation, etc.—otherwise any change observed may merely be a reflection of a difference in the patient's weight. Lastly, if in a group of subjects one wants to know whether variations in their ventilation may be due to disturbed cardiopulmonary function a standardized test must be used; or, again, the variations may simply reflect differences in their weights.

Apparatus and Method

Standardizing the Exercise.—Since the external mechanical work performed in a step-test is a product of the patient's weight and the height and rate of stepping, it is evident that altering either the height or the rate of stepping can compensate for differences in weight between one patient and another and so keep the amount of work constant. However, the range of variation in weight that is commonly encountered is such that if stepping rate only were altered the lightest of subjects would have to step so quickly and the heaviest so slowly that the comparison between them would not be fair, since their physiological efficiency would not be comparable. Similarly, unfair comparisons might be made if only the height of step were changed. But if both height and rate

FIG. 1.—Nomogram for determining appropriate combinations of height and rate of stepping so that all subjects do the same amount of work in the step-test independent of their weight.

are altered to compensate for weight variations, large adjustments of either can be avoided. The appropriate height and rate of stepping are quickly found without calculation by using the nomogram reproduced in Fig. 1.*

The nomogram is used by placing a ruler on scale A at a point corresponding to the weight of the subject, and the ruler is then adjusted so that it passes through the amount of work chosen on scale B. The place where it intersects the reference line C is marked. The ruler is then laid across the scales D and E in any position, provided that its edge passes through the point marked on line C. The readings thus obtained from D and E will give a combination of height and rate of stepping which will ensure that the subject performs the chosen amount of work.

In preparing the nomogram scale E was limited so that its extremes were within the flat-topped part of the well-known curves relating rate of muscular contraction and physiological efficiency (Lupton, 1923; Garry and Wishart, 1931). Scale D was limited so as to avoid large changes in knee-angle and hence in available leg-thrust (Hugh-Jones, 1947). If the ruler is kept reasonably horizontal through the point found on scale C, any changes in physiological efficiency between one subject and another due to change in height and rate of stepping will be minimized. It has been found experimentally that, even when the extremes of the height and rate lines are used, efficiency is not appreciably affected (see the results of the appraisal of the test below).

Fig. 2.—The apparatus. b=½-in. (1.25 cm.) boards for altering height of step. g=Gas-meter. m=Metronome. s=Stand. (Note: It is convenient to fit a sloping bar of wood (w) to the stand, as shown, and to slot the boards (b) in the appropriate place to fit against this bar. The boards can then only be placed on the step in a definite order so that each can be marked with the height of step formed when it is at the top of the pile.)

*Full-size photographic copies of the nomogram (10 by 8 in.—25 by 20 cm.) are available on application to the Director, M.R.C. Pneumoconiosis Research Unit, Llandough Hospital, near Cardiff. Price 2s.

Equipment.—Three simple pieces of equipment are used for the test (Fig. 2): (1) a metronome for controlling the rate of stepping; (2) a low rigid stand or platform, about 15 by 12 by 9 in. (38 by 30 by 22.8 cm.) high, whose height can be altered in ½-in. (1.25-cm.) increments by placing the appropriate number of ½-in. (1.25-cm.) boards on it; and (3) a low-resistance domestic type of gas-meter fixed to the platform at about elbow-height standing. This meter faces away from the patient using the step. It is modified by replacing its multiple small dials by a single large dial and pointer which is so geared that one revolution corresponds to 50 litres of gas passing through the meter, the dial being calibrated so that it can be read to the nearest half-litre. The pointer can be reset to zero manually. A mouth-piece and two-way valve are connected to the gas-meter by corrugated tubing from the valve outlet; the patient holds the valve in the hand while using the mouth-piece.

Procedure.—The patient is weighed and the step and metronome are each adjusted to the values selected from the nomogram. It is convenient to set the metronome at four times the stepping rate so that when exercise starts the left foot is raised on to the step in time with one click of the metronome, the right foot is then brought to it on the second click, the left foot returned to the ground on the third, and the right foot returned on the fourth, and so on. Using the metronome in this way makes it easier for the patient to keep time. While the test is being explained and demonstrated to him the patient rests in a chair. He puts on a nose-clip and gets used to breathing through the mouthpiece. The observer then records the cumulative readings of the gas-meter every half-minute for at least three minutes of rest. The metronome is started and the patient completes five minutes of exercise-stepping followed by about five minutes of recovery, during which he again sits at rest. During both the exercise and the recovery period the observer continues to record the half-minute meter readings until constancy in consecutive readings shows that recovery is complete.

Work-level Used.—For general purposes 350 kg.m./min. has been used for the five minutes of exercise. This level means that the exercise is not limited by muscle fatigue. It was chosen to provide enough exercise in fit subjects to provoke an accurately measurable ventilatory response, yet allowing the test to be completed by all but the most seriously disabled patients. Since the results can be expressed so that retesting at a lower level of work is unnecessary even if patients fail to complete the full five minutes of exercise (see below), this one work-level has been satisfactory. However, if only very seriously disabled patients were to be tested a lower level of work might be preferable.

Expression of the Results

In Fig. 3 the results of a typical exercise test in a normal subject are shown graphically in order to simplify description of the terms to be used. Differences between the successive cumulative readings of the gas-meter, which are the volumes of air exhaled in successive half-minute periods, have been plotted against time. The ventilation, which is constant at rest, increases during the first two or three minutes of exercise until a "steady state" is reached. When the exercise ceases the ventilation returns to the resting level. In patients who complete the exercise (the majority), with the venti-

FIG. 3.—A typical result of the exercise test in a normal subject shown graphically to facilitate description of the terms used (see text). R.V.=Resting ventilation (ordinate $\times 2$, litres/minute). E.V.=Exercise ventilation at a steady state (ordinate $\times 2$, litres/minute). a =Area of replacement of ventilatory debt. (a' is an equivalent area.) Shaded area=Excess volume of air used as a result of the exercise (E.E.V.). Standardized excess ventilation (S.E.V.)= $\frac{(E.E.V.)}{\text{Time of Ex.}}$ i.e., average ventilatory cost (litres/min.) for each 350 kg.-m. of work done. Standardized ventilation (S.V.)=S.E.V.+R.V.

lation at a steady state, the "exercise ventilation" (E.V.) can be simply taken as a measure of the ventilation resulting from the exercise.

A few patients cannot, or will not, complete the full five minutes of exercise, and in these cases the E.V. is not an appropriate measure. However, in all patients the ventilatory cost of whatever work is done is the total increment of ventilatory volume during exercise and recovery above the initial resting level. This value, the "exercise excess volume" (E.E.V.), is represented by the area shaded in Fig. 3. Divided by the time of exercise it represents the average ventilatory cost of each 350 kilogram-metres (kg.-m.) of work which is completed. This average value is called the "standardized excess ventilation" (S.E.V.). The sum of the S.E.V. and the resting ventilation (which is comparable with the E.V.) is called the "standardized ventilation" (S.V.); it is an appropriate measure of ventilatory cost in all cases (see paragraph on the relation between the S.V. and E.V. below).

In practice the test results need not be graphed. The successive meter readings are recorded, together with their differences. The E.V. is then taken as the average difference in meter readings during the last three or four half-minutes of exercise over which the differences are approximately constant. This value is doubled, and so expressed in litres/minute. The S.V. is calculated as follows: the excess ventilatory volume of air used on account of the exercise (E.E.V.) is found by subtracting from the final meter reading the volume of air which would have been exhaled at rest during a corresponding period of time (the latter being got from the meter-reading at the end of the initial period of three minutes' rest by proportion); this volume is standardized by dividing by the time of exercise, and so expressed in litres/minute, and then added to the resting ventilation (R.V.). All gas volumes are expressed as saturated with water vapour at body temperature by multiplying by the appropriate factor given in Table I.*

Thus, in summary, the results obtained from the cumulative readings of the gas-meter as measures of the ventilatory cost of the work are: (1) the S.V., which is the sum of the S.E.V. and R.V. and is appropriate in

all cases; and (2) E.V., which is simpler but appropriate only when the patient completes the full five minutes of exercise.

TABLE I.—Factors by Which Gas Measurements Recorded at Varying Room Temperatures are Multiplied for Correction to Body Temperature

Temp. °C.	Factor	Temp. °C.	Factor	Temp. °C.	Factor
16	1.119	21	1.090	25	1.069
17	1.111	22	1.085	26	1.063
18	1.107	23	1.080	27	1.057
19	1.101	24	1.074	28	1.051
20	1.097				

Relation Between the Standardized and Exercise Ventilation

The relation between the S.V. and the E.V. can be deduced from Fig. 3. Since the ventilatory debt, which accumulates at the beginning of exercise before a steady state is reached, is repaid quantitatively after the exercise ceases (Hill and Lupton, 1923), the area (a) can be represented by an equivalent area (a'), so that the excess volume of air used on account of the exercise (E.E.V.) is represented by the area outlined in dots. Hence in subjects who achieve a "steady state" the S.V. (which is represented by any one of the five rectangles between the minute abscissae during the exercise period and the upper dotted line of the E.E.V. rectangle) should be identical with the E.V. The agreement between the two is found to be very close in practice (see Fig. 5 and discussion of results).

But if a subject stops the exercise before a steady state is reached the S.V. will then be greater than any level of ventilation actually achieved. Thus, if the patient in Fig. 3 had elected to stop the exercise after only two minutes, when his ventilation was 9 litres in the half-minute, the

FIG. 4.—Results of standard exercise tests on each of two normal subjects and one with advanced emphysema (subject 3). All subjects did three tests with respectively one, three, and five minutes of exercise. Shaded rectangle=Resting ventilation (R.V.). Clear rectangle=Standardized excess ventilation (S.E.V.). Standardized ventilation (S.V.)—that is, S.E.V.+R.V.—is given in figures above each rectangle.

*It is assumed that the gas in the meter is at room temperature. This assumption is not quite true, but correcting for variations in room temperature in this way leads to negligible error.

total ventilation in excess of the resting level would still represent the ventilation due to the exercise (though in this case only a total of 700 kg.-m. instead of the full 1,750 kg.-m.—350 kg.-m. $\times$ 5 minutes), so that, when standardized, the ventilatory rate (or S.V.) would be the same as before.

When the level of exercise is an "overload," in a seriously disabled patient, the same argument applies: the ventilatory debt continues to increase the longer the exercise goes on; the patient is forced to stop, and pays back the debt by spreading an increase of ventilation over a number of minutes during recovery. The S.V. then represents a ventilatory rate greater than that which could be maintained or even achieved by the patient, for if this were not so a "steady state" rather than further debt could have been reached by continuance of the exercise.

Since the S.V. is theoretically independent of the time of exercise, why should we not be satisfied with less than five minutes of exercise? The reason is that small increments of ventilation over the resting level are difficult to detect. This point is demonstrated, and the above theoretical discussion justified, by an experiment in which two normal subjects and one subject with advanced emphysema, who could only just manage five minutes of exercise, performed three tests at the standard rate of 350 kg.-m./minute, but for one, three, and five minutes of exercise respectively. The results are shown in Fig. 4. It will be seen that the S.V. is reasonably independent of the time of exercise, though it tends to be smaller the shorter the exercise, so that when only one minute of exercise is performed it is an underestimate by about 10% of the value for five minutes' exercise. At three minutes there is an underestimate (5%) only in subject 3. Thus the standardized ventilation of subjects so disabled as to be unable to do more than three minutes of exercise at the low rate used in the test (a small minority in practice) is likely to be an underestimate of their ventilatory cost, which in these cases may be very large.

The underestimate in very short periods of exercise probably arises because the shorter the exercise the greater the relative contribution of the recovery ventilation to the total ventilatory cost, and recovery ventilation cannot be assessed very precisely because small elevations of ventilation over the resting level will be missed and the recovery period will then not be fully recorded.

There is no purpose in prolonging the exercise beyond five minutes, because any patient who is capable of achieving a steady state at the level of exercise used will have

done so, and once this steady state has been achieved no greater precision will be obtained for the standardized excess ventilation.

Validity of the Test

The nomogram enables all subjects to be given a constant amount of external mechanical work, but is it true that subjects do a constant amount of physiological work? In other words, is the physiological efficiency the same over different portions of the nomogram? In order to determine this and to find the repeatability of the test, an experiment was designed as shown in Table II.

Three subjects, who were chosen to cover a fairly wide range in weights, performed the test daily during two periods of three days each. On each day the test was done three times (at 10 a.m., 2 p.m., and 4 p.m.) with different step-heights representing high, medium, and low values on the height scale of the nomogram, each height being used with the appropriate stepping rate to give the standard amount of work. The experiment was randomized as shown in Table II. The results of the experiment are given only in terms of the exercise ventilation, as all subjects completed the full five minutes of exercise and reached a steady state.

An analysis of these results is shown in Table III, in which the average values of the E.V. for comparable groups of results are given.

It will be seen from Table III that the method of standardizing the work is fully justified experimentally, since high, medium, and low heights of step, combined from the nomogram with appropriate slow, medium, and fast stepping rates respectively, lead to almost identical exercise ventilation rates. This experimental demonstration of the physiological validity of the nomogram confirms the conclusions of Passmore and Thomson (1950) that "stepping is a muscular movement with a very broad optimum of efficiency both as regards rate of stepping and height of step." They found a wide maximum of efficiency at rates between 14 and 18 steps a minute on a 10-in. (25-cm.) step.

	{E.V.	29.4	27.4	27.3	24.1	26.2	25.1	20.3	21.2	21.9
15/2/50	{Time	10 a.m.	4 p.m.	2 p.m.	4 p.m.	2 p.m.	10 a.m.	2 p.m.	10 a.m.	4 p.m.
	{E.V.	28.4	28.4	29.4	24.0	25.1	25.1	20.7	21.8	21.8

It is also seen from Table III that the test provides an objective measure of ventilatory cost which is highly repeatable, not being materially affected by the time of day or by variation between one day and another, though a full analysis of variance on the data showed the variance between days to be statistically significant.

Measurement of Breathlessness

We still have to relate the ventilatory cost of the standard exercise to the symptom of exertion dyspnoea. It is generally agreed that "breathlessness" is noticed with increasing severity the more nearly a subject's ventilation approaches the maximum of which he is capable. Thus to assess breathlessness on exertion the results of the exercise test must be related to the subject's maximum ventilation. The latter can be most conveniently measured on voluntary hyperventilation (Gray *et al.*, 1950, review the evidence for this), and it is then called the maximum breathing capacity (M.B.C.) or maximum voluntary ventilation (M.V.V.). Thus the relation between a patient's ventilation at a given state of exertion to the M.V.V. has been called a "dyspnoeic index": for if a patient's ventilation is only, say, 20% of his maximum, he is not very breathless, while if it is, say, 80%, then he is severely dyspnoeic. This, or a similar index, has been widely used by previous workers—for example, Kaltreider and McCann, 1937; Hannon, 1945; Warring, 1949; Baldwin *et al.*, 1949a, 1949b; Matheson and Gray, 1950; Pachner, 1950).

The Two Indices of Dyspnoea

By relating the results of the standard exercise test to the patient's M.V.V., two indices of dyspnoea are obtained:

The first dyspnoeic index (D.I.₁) is that used by previous workers:

$$\text{D.I.}_1 = \frac{\text{E.V.} \times 100}{\text{M.V.V.}}$$

The second index (D.I.₂) is the relation not of the exercise but of the standardized ventilation to the maximum:

$$\text{D.I.}_2 = \frac{\text{S.V.} \times 100}{\text{M.V.V.}}$$

The relation between these two indices is shown in Fig. 5, which is a scatter diagram of the results obtained from 228 subjects ranging from young normal men to men with severe pneumoconiosis, emphysema, and heart failure, so that all degrees of breathlessness on exertion are covered.

The value used for the patient's M.V.V. was the same in each index and was measured independently of the exercise test, all measurements being corrected to body temperature. The apparatus used has already been described (Gilson and Hugh-Jones, 1948-9).

It will be seen from Fig. 5 that in all patients who completed the full five minutes of exercise (185 out of the 228, shown as dots) the two indices agree very closely, the continuous line in the figure representing perfect agreement. This means, since the denominator

FIG. 5.—Scatter diagram showing the relation of the two alternative indices of dyspnoea obtained from the exercise test and measurements of the maximum voluntary ventilation (M.V.V.) on 228 subjects who covered a wide range of dyspnoea on exertion

$$(\text{D.I.}_1 = \frac{\text{E.V.}}{\text{M.V.V.}} \times 100. \quad \text{D.I.}_2 = \frac{\text{S.V.}}{\text{M.V.V.}} \times 100).$$

(Note: only 193 points are shown on this diagram, since the points would be superimposed in 35 out of the 228 subjects.)

of both indices is the same in any one patient, that the E.V. and S.V. are the same provided a steady state is reached; we have seen that this should be so theoretically.

Consider now the first dyspnoeic index (abscissae). First of all, by definition, this should not exceed 100%, since the M.V.V. is taken to represent the patient's maximum possible ventilation (Gray *et al.*, 1950). In fact, 10 of the 219 cases show an index greater than this. In these cases either full co-operation was not obtained in recording the M.V.V. or in a few very disabled men an exercise overload may create greater hyperventilation than the patient can bring himself to achieve voluntarily: these 10 patients were all very disabled and only two completed the exercise. Secondly, in subjects who do not reach a steady state an index obtained by using the maximum level of ventilation as a substitute for the true E.V. at a steady rate is false, for this ventilation results from less exercise than that of other subjects.

Now, if we consider the alternative D.I.₂ (ordinates) it is evident that it may, and should, exceed 100% in a few cases. We have seen that very disabled subjects may spread a debt of ventilatory cost over a number of minutes which, when standardized by relating the total excess ventilation in exercise and recovery to the exercise time, gives a ventilatory rate (S.V.) greater than that of which they are capable.

It is probable that the subjects who failed to complete the five minutes of exercise and had a D.I.₂ of below about 80% in Fig. 5 could have completed it and reached a steady state had they been prepared to tolerate

the feeling of dyspnoea, since an approximately equal number of such subjects did so. They would have increased their exercise ventilation, and their "D.I.₁" would have been increased to the correct figure. In those who failed and in whom the S.V. was greater than that which could have possibly been replaced at a steady state because of their maximum ventilatory limit, the index exceeds 100%.

The broken line in Fig. 5, about which all the points scatter, has been inserted, since it may aid the concept of the ventilation on exercise being unable to exceed a limit set by the maximum ventilatory capacity (100% D.I.₁). The continuous straight line of agreement between the indices means a steady state or "pay as you go"; the broken line represents a departure from this by stopping exercise as the limit of ventilation is approached and breathlessness becomes intolerable. A greater proportion of the ventilatory debt is then spread into the recovery period by those who fail, giving an S.V. increasingly large compared with the E.V. and hence an increasingly large D.I.₂.

In summary: by comparing the S.V., instead of the E.V., with a subject's M.V.V. we obtain an index of dyspnoea (D.I.₂) which is practically identical in all subjects who complete the 5 minutes' exercise with the index commonly used (D.I.₁). The new index of dyspnoea has the advantage of being applicable even if the subject fails to complete the exercise, provided two or three minutes are done to give a reasonably reliable estimate of the S.V.; thus the necessity for repeat testing at different exercise levels is avoided. When the subject cannot achieve a steady state, at the exercise level used, the D.I.₂ may exceed 100%.

Is the dyspnoeic index in practice related to the symptom of breathlessness? Kaltreider *et al.* (1937) found the usual index (D.I.₁) to be well related to subjective dyspnoea. Baldwin *et al.* (1949a) found "a clear-cut correlation between the severity of dyspnoea as recorded in each patient's history" and their "breathing reserve" (which is the complement of the D.I.₁—that is, $\frac{M.V.V. - E.V.}{M.V.V.} \times 100$) though subsequently Baldwin

et al. (1949b) found the threshold of breathlessness on this index to be lower in cases of emphysema than in other patients. However, in their index the ventilation during the first minute of recovery after only one minute of exercise is used as an expression of exercise ventilation.

In our 228 subjects the indices showed a general relation to symptomatic "breathlessness." Fig. 6 is a scatter diagram relating the D.I.₂ to the clinical grading of the patients into four approximate grades of breathlessness by Dr. C. M. Fletcher on the basis of the following standard questions:

Grade 1: Is patient's breath as good as that of other men of his own age and build at work, on walking, and on climbing hills or stairs?

Grade 2: Is patient able to walk with normal men of own age and build on the level but unable to keep up on hills or stairs?

Grade 3: Is patient unable to keep up with normal men on the level, but able to walk about a mile or more at his own speed?

Grade 4: Is patient unable to walk more than about 50 yards on the level without a rest?

Grade 5: Is patient breathless on talking or undressing, or unable to leave his house because of breathlessness? (Not used for test.)

FIG. 6.—Scatter diagram relating the second dyspnoeic index (D.I.₂) of 228 subjects to a grade of "breathlessness" as determined independently from clinical history.

• There is a general agreement between the measured dyspnoeic index and patient's reply to the questions about his breathlessness.

The dyspnoeic index is plotted on a logarithmic scale for convenience. On a "straight" plot the relation between index and grade is non-linear, patients in the lowest clinical grades often having particularly large indices of dyspnoea. This effect may be due to the scale of grading, since scales of judgment are frequently non-linear. Moreover, on a straight plot there is a skewed distribution within each grade, especially in the first, which may have resulted from the dyspnoeic index having a limiting value of about 12% at the lower end, which represents the minimum ventilation at this level of exercise.

Normal Values.—Since the exercise results (the E.V. and the S.V.) are compared with the subject's M.V.V. to give an objective measure of breathlessness their "normality" *per se* does not arise. However, since one may wish to know whether a patient's exercise ventilation itself is excessive or not—for example, in the assessment or treatment of heart failure as is discussed below

TABLE IV.—Average Value of the E.V. and S.V. Resulting from the Exercise Test, Together with the Corresponding Indices of Dyspnoea, in Four Different Age Groups of Normal Subjects and a Group of Athletes (Numbers in Parentheses Represent the Range of Values Found)

Age	No. of Subjects	M.V.V.* (l./min.)	E.V. (l./m.)	D.I. ₁ ($\frac{E.V.}{M.V.V.} \times 100$)	S.V. (l./m.)	D.I. ₂ ($\frac{S.V.}{M.V.V.} \times 100$)
Athletes (O.U.A.C.) 23 years	17	187 (156–228)	30 (24–35)	16 (12–20)	27 (19–34)	15 (11–18)
Normal subjects 25 years	10	151 (125–178)	25 (19–33)	17 (11–26)	27 (22–33)	18 (13–27)
35 years	10	145 (75–176)	25 (19–36)	18 (13–25)	26 (20–37)	19 (14–29)
45 years	10	131 (102–149)	24 (20–30)	18 (13–27)	25 (22–30)	20 (14–23)
55 years	10	118 (83–157)	26 (22–31)	22 (16–28)	28 (21–38)	24 (18–30)

* Subsequent re-calibration of the M.V.V. apparatus shows these results may be slightly high. The error does not affect the conclusions.

—the values in 40 "normal" subjects, 10 in each of four age groups, is given as Table IV. The normal subjects were men most of whom were temporarily attending the Ministry of Labour's Employment Exchange in changing from one job to another. Only men with abnormal chest radiographs, hypertension, or clinical evidence of heart or renal disease were excluded. The results of testing 17 medium-distance runners of the Oxford University Athletic Team, whom we examined through the kindness of Dr. R. W. Parnell when he was investigating their physique (Parnell, 1951), are also included as the upper limit of "normality." It will be seen that the E.V. and S.V. are a very stable value not related to age, and decline in the dyspnoeic index, associated with the increasing breathlessness of ageing, is due to decrease in the ventilatory reserve as measured by the M.V.V.

Discussion and Conclusions

When this standard exercise test is to be used for measuring breathlessness it should ideally always be combined with some independent measurement of the patient's maximum ventilation such as the M.V.V., because breathlessness may arise either from a reduction in the maximum or from an increase in the exercise requirements, and only the latter can be measured by the test. In coal-workers' pneumoconiosis, for example, abnormal breathlessness on exertion, the cardinal symptom of the disease, is almost entirely due to reduction in the ventilatory capacity; excessive exercise ventilation does occur, however, mostly in men who have some evidence of right-sided heart failure (Gilson and Hugh-Jones, 1952), so that in this disease the exercise test is necessary to avoid error which would arise if the maximum voluntary ventilation alone were used for the objective assessment of breathlessness. In general cases of heart failure, on the other hand, abnormal E.V. is an important cause of breathlessness, and may be one of the earliest signs even when oxygen consumption is still normal (Harrison and Pilcher, 1930). In this case the measurement of the S.V. by the exercise test may itself provide a convenient objective method of assessment, though it should be supported by tests of maximum ventilatory capacity if occasional error is to be avoided.

One obvious effect, which might be thought to lead to error in the test, is hyperventilation through nervousness, mouthpiece resistance, etc. It certainly may cause an increased resting ventilation (R.V.) and then an apparently small exercise excess volume of air (E.E.V.). This means that the latter, which might otherwise be used as a measure of the test efficiency of the subject, may be erroneous. However, this reciprocal relation between the increased resting ventilation and the diminished volume of air caused by the exercise is such that their sum, the S.V., remains correct. Many cases of "nervous" hyperventilation occurred in the normal subjects among the 228 men examined and reported here, yet it was seen from Fig. 4 that their S.V. and E.V. agreed very closely.

In conclusion, the exercise test described in this paper has advantages in providing a known amount of work for the subject, comparable with a bicycle ergometer, but using only simple apparatus; a "submaximal" test which is not distressing for the patient or as time-consuming for the observer as testing maximal response; a valid quantitative result in the S.V., whether the patient completes the test or not provided two or three

minutes of exercise is done. The S.V. is little disturbed by subjective influences, and its use means that repeated exercise tests are not required, as they are when the amount of work is varied to give a constant response.

Summary

A simple step-test is described which enables a patient to be given a known and standard amount of exercise, comparable to exercise on a bicycle ergometer, without the use of complex apparatus. The standard exercise is achieved by adjusting both the height and the rate of stepping to compensate for variations in weight between one patient and another, the appropriate values being got from a nomogram without calculation.

The exercise period is five minutes. A suitable work load is usually 350 kg.-m./minute.

The patient's ventilatory response is recorded with a domestic gas-meter. This is expressed as a "standardized ventilation" (S.V.), which is got from the ventilation in excess of the resting level during both exercise and recovery and gives a valid measure even if the patient cannot or will not complete the five minutes' exercise. In all subjects who complete the test the S.V. is numerically equal to the exercise ventilation (E.V.) at a steady state.

For measuring the symptom of breathlessness the ventilation caused by the exercise should be related to the patient's maximum voluntary ventilation (M.V.V.) measured independently. A dyspnoeic index $\left(\frac{S.V. \times 100}{M.V.V.}\right)$ is suggested as an alternative to the index previously used by other workers—namely, $\frac{E.V. \times 100}{M.V.V.}$. The former index avoids the necessity for repeat testing at a lower exercise level in those who fail to complete the exercise, when the usual index becomes invalid.

We wish to thank members of the Pneumoconiosis Research Unit, especially Dr. C. M. Fletcher (the director) and Dr. J. C. Gilson, for advice and many suggestions. We are indebted to Mr. P. D. Oldham, statistician to the unit, for his help in constructing the nomogram and designing the experiments.

LATE RESULTS OF PERURETHRAL PROSTATIC RESECTION

BY

T. L. CHAPMAN, Ch.M., F.R.C.S., F.R.F.P.S.

Urological Surgeon, Victoria Infirmary, Glasgow, Hairmyres Hospital, Lanarkshire, and Ballochmyle Hospital, Ayrshire

AND

J. W. SUTHERLAND, M.B., F.R.C.S., F.R.C.S.Ed.

Registrar, Urological Unit, Victoria Infirmary, Glasgow

Advances in the open surgery of prostatic obstruction have distracted attention from the merits of the perurethral approach. Harris (1929) and Wilson Hey (1946) have shown the advantages of closing the bladder, and Millin (1945) has demonstrated the advantages of not opening the bladder at all. Surely it is better still to leave the abdominal wall intact.

The immediate results of perurethral prostatic resection are recognized to be good. This operation has a very low mortality, and its value in this respect is greater than can be shown by figures, for many general surgeons enucleate the straightforward case themselves but refer the "bad risk" to the urologist for perurethral treatment. The use of thrombin has eliminated the frequent wash-outs of the bladder which were considered necessary and has reduced enormously the incidence of clot retention. Suction evacuation has shortened the duration of the operation and facilitated the treatment of larger glands. Isotonic irrigating fluids have eliminated post-operative anuria—never a common complication, but a grave one. Many patients experience merely the minimal discomfort associated with a modern anaesthetic and a few days of catheter drainage. The present investigation is an attempt to assess the late results, on which the reputation of this operation clearly depends.

Indications

The patients were treated by the "punch" type of operation, using the Gershom Thompson resectoscope. This is the operation which has achieved superlative results at the Mayo Clinic. The indications varied a little at different times, but a high proportion of the patients were treated perurethrally throughout. In the last 400 cases referred to the urological units at the Victoria Infirmary and Hairmyres Hospital the mortality was 3.25% (13 cases). Table I shows all cases of prostatic

TABLE I.—Treatment of All Cases of Prostatic Enlargement

Expectant treatment	138 cases
Endocrine treatment only	27 "
Catheter drainage only	9 "
Perurethral resection	400 "
One-stage suprapubic prostatectomy	18 "
Two-stage	11 "
Retropublic prostatectomy	5 "
Permanent suprapubic cystostomy	26 "
Catheter drainage (admitted in extremis)	23 "

enlargement referred to these units during the same period and gives an impression of our present practice. "Expectant treatment" includes those cases referred on account of prostatic enlargement without signs of obstruction and with only mild symptoms. This group has been discussed more fully elsewhere (Chapman, 1949). "Endocrine treatment only" includes cases of carcinoma of the prostate in which obstructive symptoms were not marked. "Catheter drainage only" includes

cases in which bladder function was resumed after a short period of catheter drainage, and in which the patient refused operation or was advised against it. Several of these were cases of acute retention in the post-operative phase of some other condition.

Suprapubic prostatectomy was performed when the gland was exceptionally large, or when complicated by large diverticula, or when the urethra would not accommodate the instrument with ease. When stones accompanied prostatic obstruction, litholapaxy and prostatic resection were performed if both the stone and the prostate were of moderate size. Four of the five retropublic prostatectomies were performed by a deputy doing holiday duty. Permanent suprapubic cystostomy was advised for the "very bad risk" patient. The final item of the Table includes patients whose prostatic obstruction proved to be only an incident in the final stage of some other disease. Of all patients whose prostatic disease was severe enough to require operation and whose general condition justified the removal of the obstruction, 92% were treated by perurethral prostatic resection.

Description of Present Investigation

In this investigation we are concerned with late results, and patients treated since 1949 are not included. Efforts have been made to maintain contact with all patients. Postal questionnaires were sent out on five occasions—December, 1941, April, 1945, June, 1946, August, 1948, and August, 1950. Patients who had changed their address or who failed to respond were usually traced by the almoner's department of the Victoria Infirmary. If the reply to a questionnaire suggested unsatisfactory progress the patient was asked to attend for examination. In 1948 an attempt was made to see all surviving patients. Of the 497 patients traced, 28 died within a year of operation and are not considered except in the discussion of cause of death. In six cases in which the operation was performed in the hope of removing a suprapubic tube an unsatisfactory result was obtained and the tube was retained. In two cases frequent micturition persisted after the operation, and the patient sought advice elsewhere. In both cases an enucleation operation was performed and the frequency persisted. The convenient explanation was given that damage had been caused by the perurethral resection. Both were cases in which frequent micturition was the chief symptom and the evidence of obstruction was not great. It is sometimes justifiable to operate for frequent micturition alone, but it is common experience that disappointing results occur in this group.

The remaining 461 cases are tabulated in Table II. In the cases of nodular hyperplasia an attempt was made to remove all glandular tissue. No doubt this has been

TABLE II.—Duration of Follow-up

Duration in Years	Cases of Nodular Hyperplasia	Cases of Median Bar	Cases of Carcinoma	Total No. of Cases
13+	1	—	—	1
12-13	9	—	—	9
11-12	10	—	—	10
10-11	13	—	—	13
9-10	12	5	—	17
8-9	22	2	2	26
7-8	22	2	—	24
6-7	26	2	—	28
5-6	34	3	3	40
4-5	39	3	4	46
3-4	39	3	2	44
2-3	68	5	13	86
1-2	100	6	11	117

more successful in the later than in the earlier cases. In the median bar cases only a small quantity of tissue was removed. In the carcinoma cases variable quantities were removed, sufficient to produce a wide channel. Since 1942 these patients have also received stilboestrol treatment. Table II shows the duration of follow-up—that is, the period between operation and the time of writing in the case of survivors, or the period between operation and the date of the patient's death.

Deaths During Follow-up

Table III shows the cause of death in those patients who died within a year of operation and who have not been considered in the general discussion. It is probable

TABLE III.—Cause of Death Within One Year of Operation

that the original condition or the operation for its treatment was responsible for death in the four cases in which death was due to urinary infection and to uraemia. In one case in which the prostate was apparently benign at the time of operation and in two cases in which malignancy was known to be present the patient died of secondary malignant disease. In the remaining cases there appeared to be no association with prostatic obstruction or its treatment.

Table IV shows the cause of death in those patients who have survived more than a year. In nine cases death was due to urinary infection or to uraemia, and these again must be associated with prostatic disease. One patient who had an apparently benign prostate and five who had definitely malignant prostates died of secondary carcinoma. In the remaining cases there was no obvious connexion.

Results in General

In most cases the patient was very well pleased with the function of the bladder. The results as judged by day and night frequency, force of the flow, control of the flow, and the effect on general health were excellent throughout the period of observation. If doubt arose bacteriological examination of the urine, intravenous

pyelography, and endoscopic examinations were performed. Complications have occurred, and these are considered individually.

Recurrent Prostatic Obstruction

Many believe that the effects of perurethral prostatic resection are temporary or even brief. For example, Grant and Lich (1948) write about the "enormous percentage" of recurrent cases, and we have been asked quite seriously how many times it is necessary to repeat this operation in the course of a year in order to keep a patient free from obstruction. This impression is often due to confusion between benign prostatic enlargement and an active malignant process where a few cells left behind will grow in an uncontrolled manner. It has been shown by Moore (1936, 1943) that the process of involution in the prostate goes on with the greatest rapidity before the age of 60, and that the aetiological agent which produces benign hyperplasia is most active before that age. One of us has demonstrated this fact in a follow-up, extending over ten years, of patients who had received no treatment at all (Chapman, 1949).

In the group of patients discussed here 18 have had a second operation for recurrent prostatic obstruction, and to these must be added five patients who had been operated on elsewhere, probably for obstruction, and two patients treated in other units in whom obstruction is known to have occurred, although no operation was advised. Two patients who had previously had resection for median bar returned after intervals of seven and ten years, showing signs of obstruction which proved to be due to lateral lobe enlargement; there was no evidence of recurrence of the bar formation, and the lateral lobes had enlarged during the interval. These two cases need not be considered in a discussion of recurrence of benign prostatic enlargement.

The incidence of recurrence was much higher in patients followed up for more than ten years. This is not due merely to the longer follow-up. In the earlier stages of his experience an operator removes less tissue. In the units discussed here 14 g. was an average resection in 1938; 50 g. resections are now fairly common. Of 116 cases of benign hyperplasia followed up for a period of five to ten years, seven have recurred, a rate of 6%. This is much lower than is usually suggested by the detractors of this operation. Of 246 cases of benign hyperplasia followed up for one to five years, five (2%) recurred. This is a clear demonstration of the great value of the operation in patients whose expectation of life is short. Local recurrence of obstruction in malignant cases has not been common. Possibly stilboestrol treatment is responsible to some extent for this. It must be noted, however, that only two malignant cases survived for more than six years.

Most urological surgeons treat many of their papilloma cases by multiple perurethral diathermy treatments, yet suprapubic, perineal, and retropubic prostatectomists join in their cries of horror at the thought of a second resection of prostatic tissue, however small. This would be less surprising if the open operations were free from the risk of recurrence themselves. Millin (1942) found in his records 53 cases of post-prostatectomy obstruction after suprapubic operations by various surgeons. Emmett (1944) found records of 102 patients who had suffered from recurrent obstruction after suprapubic and perineal operations. The retropubic operation, so recently devised, has already had recurrences.

By far the most important point about recurrence after perurethral prostatic resection has yet to be mentioned. In most cases the correction of the recurrence is a trivial matter both for the surgeon and for the patient. The amount of tissue to be removed is quite small and the operation quite short. With one exception these operations for recurrent obstruction have been free from trouble, and most of the patients have not regarded the experience as a surgical operation.

Second Operation for Symptoms other than Obstruction.—Six patients have had a second operation for reasons other than obstruction. One patient had attacks of haematuria at intervals, and it was thought that the removal of a few remnants of prostate might reduce this tendency. He continues to have occasional haematuria, though his general health is good. Four had persistent frequent micturition, and a second resection was performed in the hope of relieving this. Some benefit resulted in these cases, though there was no evidence of recurrent obstruction. One patient who had heavily infected urine before his operation did not improve much after his resection, so a second small resection was tried, also without much effect.

Post-operative Stricture

Millin (1947) comments on the "high incidence" of post-operative stricture after perurethral prostatic resection, and Grant and Lich (1948) describe it as a "frequent sequela." In the present series of 461 cases nine post-operative strictures have occurred. Two of these required to have the stricture excised and one had an external urethrotomy. All attend at intervals for bougie dilatation; in three cases the interval has been extended to one year. The most recent answers to questionnaires in these nine cases show that six have no difficulty in micturition, one has some difficulty in the morning, and two notice a weakening of the flow before they attend for bougie treatment. One of them passes urine at intervals of two hours; the others have intervals of three or more hours. This complication is not a major catastrophe, but it is a very unpleasant experience, and all steps should be taken to avoid it.

Urethral bougies passed without force do not influence the calibre of the normal urethra, but they seem to facilitate the passage of the resectoscope. This may be the result of thorough spreading of the lubricant. They also show when the instrument ought not to be passed. For many years American surgeons have used resectoscopes through a perineal stab when the lumen of the urethra was not adequate. An unfounded fear of fistula formation deterred us from the use of this method for many years. Recently, on the strong recommendation of T. J. D. Lane, we have used it with success.

Incontinence of Urine

Urinary incontinence has occurred after all types of prostatic operation and is said to be commoner after perurethral procedures. The present investigation appears, at first glance, to support this view, as seven patients require to wear incontinence bags. This impression is modified by further consideration. Three of these patients had carcinoma of the prostate and were incontinent before their operation. The disease rather than the operation appears to be responsible in these cases. The same may be said of another patient who had an infected prostate and was referred by a general surgeon who would have enucleated an uninfected gland. In

another there was gross fibrosis of the prostate and of the region around the bladder neck as a result of old infection. A minute resection from a prostatic bar increased the incontinence of another patient: the cause is probably neurogenic, though no definite evidence has been found. The remaining patient, a case of simple nodular hyperplasia, is probably the only one in the series in whom an enucleation was a reasonable alternative.

One patient who had persistent incontinence after resection was treated with complete success by the operation described by Millin (1939). Two other patients have had this treatment without success.

In addition to these patients a few have a slight dribbling after the act and find it convenient to wear a pad. One man gives the unusual story that his control is excellent except when he goes to sleep in a chair—a practice which could be avoided without serious results.

It is true, however, that many patients are incontinent for a few hours or days after the removal of the catheter, and in some cases this symptom has persisted for a few weeks. The detrusor has hypertrophied to overcome the obstruction, and the sudden removal of the obstruction has left the sphincter at a disadvantage. The movements of the instrument produce some stretching of the sphincter, which is sufficient in some cases to retard the recovery of its tone.

Conclusions

The complications of perurethral prostatic resection have been exaggerated, and this operation is worthy of a greater place in the treatment of prostatic obstruction in this country. Many British surgeons use perurethral resection, only in fibrous prostates, malignant prostates, and "bad risk" cases, and believe that the functional result after perurethral resection is, in general, inferior to that of an enucleation operation. Perurethral resection is selected for these groups only because enucleation is impossible. The best results by the perurethral methods are obtained in the small or moderate glandular types. The distinction between gland, bladder neck, and capsule is clear, and removal of the glandular tissue is an exact procedure. It is true that the removal of the very large gland is an extremely difficult operation, but a gland of 20–40 g. can be removed in a reasonable time, with negligible upset to the patient, by a surgeon who has been trained in this operation. We believe that the indications should include such cases, and that these constitute the majority of patients suffering from prostatic obstruction.

The open operations for prostatic obstruction have become much safer in recent years. This is one reason for the decrease in interest in perurethral operations. It is not, however, an adequate reason. It is instructive to compare the treatment of vesical calculus. The crushing of a bladder stone is a very old operation, and when it became reasonably safe to open the abdomen interest in litholapaxy decreased. The urological specialist continued to practise it, however, and there is no doubt that it is still the operation of choice for the usual bladder stone of moderate size. The only reason for another course is the absence of any surgeon experienced in the operation.

In prostatic surgery in this country it is usual to reserve perurethral resection for the case in which enucleation would be difficult or impossible. We believe that the opposite policy might be employed with

advantage—that is, to use enucleation operations only when there is a serious contraindication to the perurethral route.

Summary

Perurethral prostatic resection has been used in the treatment of over 90% of patients fit for the removal of prostatic obstruction.

We followed up 461 cases for periods of one to thirteen years, and in the great majority an excellent functional result has been maintained throughout.

Recurrent prostatic obstruction occurred in 6% of cases of benign hypertrophy followed for five to ten years and in 2% followed for one to five years.

Post-operative stricture occurred in 2% of cases and was not difficult to treat.

The operation failed to relieve incontinence in five cases and produced incontinence in two—one a nodular hyperplasia and the other a fibrosis of the prostate and periprostatic tissues of inflammatory origin.

The results suggest that the complications of perurethral prostatic resection have been exaggerated, and that this operation is worthy of a much larger place in British surgery.

Our debt to the surgeons of the Mayo Clinic is obvious. In addition we wish to thank Dr. A. B. M. Currie, Dr. W. Kraszewski, and the staff at the Victoria Infirmary, Glasgow, and Hairmyres Hospital, Lanarkshire.

INCONTINENTIA PIGMENTI

REPORT OF CASE, WITH SUMMARY OF 29 CASES FROM THE LITERATURE

BY

ALFRED WHITE FRANKLIN, M.B., B.Ch.
F.R.C.P.

Twenty-six years ago Bloch (1926) demonstrated to the Swiss Dermatological Society at Basle an 18-months-old girl with irregularly distributed bizarre-shaped pigmentation of slate colour involving the trunk and lower extremities. After histological study of the skin he gave the condition the name of incontinentia pigmenti. In 1925 Bardach had reported "systematized naevus-formation" in a pair of 17-months-old twins, undoubtedly with the same condition. Since 1926 at least 29 other cases have been reported, the details of which are summarized below. Although reports have come from Germany, Sweden, the United States (both white and black subjects), Canada, Holland, Denmark, and Japan, no case has yet been recorded in England. It is true that Kalz and Mackenzie (1947) published a case in the *British Journal of Dermatology and Syphilis*, but the child was Polish and in Montreal.

The case reported here is that of a baby who was born and lives in Hertfordshire.

Case Report

A female infant, born on February 24, 1950, was the survivor of first-born twins, eight weeks premature, the other twin being stillborn. The mother and father are unrelated, are both healthy, and there is no family history of skin disorder. The mother's father and her younger brother were each blind in one eye from babyhood. Neither survives, and the nature of the blindness is unknown.

The patient weighed 3 lb. (1.4 kg.) at birth, but was rather feeble. I saw her in her first week for this reason, and she remained in hospital for five weeks. During this time her skin was normal. Except for the skin condition described below she has been a normal girl and free from symptoms. When aged 2 months the left lower limb became swollen and red, and when two or three days later the swelling subsided a "scorch-mark" was seen by the mother. At 7 months there was another attack, the child becoming ill-at-ease and feverish, and seeming to be in pain. The left lower limb became swollen, red, and shiny; after three hours blisters appeared in the pigmented areas and a measles-like rash on the clear skin. A few days later the swelling subsided and further pigmented areas were found. When I saw her at 13 months (March 28, 1951) there had been three attacks and the lower limbs only were affected. Three

FIG. 1.—Showing the pigmentation on the chest and the narrow stripes round the trunk.

FIG. 2.—Section of skin showing a large number of melanophores containing closely packed melanin granules. (×240.)

months later, after further attacks, there was reticulated dark-brown pigmentation on the chest and abdomen.

Being quite unfamiliar with the appearance, I referred her to my dermatological colleague at St. Bartholomew's Hospital, and Dr. Brian Russell suggested the correct diagnosis.

The child is making normal progress, though her weight is only 18 lb. (8.2 kg.) at 20 months. There are no abnormal pigments in the urine. Hair, teeth, nails, and eyes are normal. There is as yet no sign of fading.

Fig. 1 shows the curious pigmentation, with the particular concentration on the chest, characteristic of the condition. There are many parallel transverse narrow stripes round the trunk. Dr. Cureton has reported as follows on a biopsy specimen of skin taken from the left chest wall by Mr. R. S. Murley: "Sections of the skin show no gross structural changes. The amount of melanin pigment in the basal layer of the epithelium is variable—one section shows a moderate amount, another shows virtually none. All sections show a large number of melanophores containing closely packed melanin granules and situated almost entirely in the superficial corium. The appearances are those described in *incontinentia pigmenti*" (Fig. 2).

Summary of Cases

Twenty-nine case reports in the literature have been studied and are summarized, together with the thirtieth case, described above.

Sex.—Twenty-six are females, three are males, and the sex in one is not stated.

Condition of the Skin.—At birth:—18 were normal, 5 had erythema with or without blisters, 2 had actual pigmentation, and 2 others had a pigmented naevus. The condition in 3 is not stated. **In the neonatal period.**—Skin lesions were reported in 11 cases (erythema in 8, skin sepsis in 3). **Pigmentation** was present at birth in 2 cases, and developed from a skin lesion or *de novo* within the first month in 9 cases, before the age of 6 months in 6 more cases, and by the age of 3 years in a further 11. The 2 remaining cases were the father of two other cases and a girl first seen at 6½ years. **Colour** is variously described as steely grey or blue, slate-grey, dark brown, light brown, or café-au-lait. Several colours may be seen in one case. **Distribution.**—The upper part of the lower limbs and the trunk, particularly in the breast region, are most often and most heavily affected, and the lower part of the lower limbs and the upper limbs less often. Lesions of the scalp have twice been recorded. In two cases (Bardach, 1925; Siemens, 1929) a yellowish band of pigment was found on the face; and in one (Fleck, 1950) there were pigment patches on the soft palate. Sometimes the distribution is symmetrical; sometimes one side of the body is more marked than the other. **Fading** is reported in 12 cases, all but one being over the age of 3 years. No comment is made in 2. In 16 there was no fading, but 9 of these were under the age of 3 years at the date of the report.

Family History.—A family history of pigmentation occurs in Bardach's (1925) twins, who were both affected, and in Nägeli's (1927a, 1927b) father and two daughters. The present case is one of twins, the other being stillborn.

Associated Congenital Defects.—Nineteen cases have no other abnormality. Six have some congenital eye defect, such as pseudo-glioma or opacity of the lens. Other defects noted are brittle or spoon-shaped nails, patchy alopecia, dental hypoplasia, congenital heart disease, microcephaly, and spastic paraplegia. The record of congenital defects in other members of the family is certainly incomplete. Sulzberger *et al.* (1938) give a family tree showing congenital blindness in many females. In my case two males in the family had some form of congenital blindness.

Histology.—The most striking feature of the histological picture of the established condition is the collection of melanin pigment in the chromatophores of the corium, often arranged round the blood vessels. There is also a disarray of the basal cells of the epidermis. In scattered areas the regular line of these cells is broken, and individual cells are seen to be small or distended and vacuolated, with deficiency or absence of the normal pigment granules. The nuclei may be pyknotic. In the earlier stage of the disease there is some oedema of the skin, with vesiculation and perivascular cell infiltration (Haxthausen, 1944). In one post-mortem report (Seidlmayer, 1942) the adrenal medulla was aplastic.

Discussion

The explanation given by Bloch (1926) is that the melanin pigment in the skin, instead of leaving the basal layer and passing out into the stratum corneum to be flaked off in wear and tear, behaves "incontinently" and descends into the corium, where it is gathered up by the chromatophores and produces "autochthonous tattooing." There is no excess of melanin production. Bardach (1925), whose cases are the earliest known at present, regarded the condition as a form of systematized naevus. Nägeli (1927a, 1927b) used the name "familial chromatophore-naevus." Siemens (1929), who gives a very clear and careful account of the histology, regarded the basal layer lesion as the primary defect and suggested the title "melanosis corii degenerativa" as a description of what was seen in the skin section in preference to Bloch's name, which described a theory of production that might prove mistaken. He believed that this is an idiopathic example of degenerative melanosis which can occur under other circumstances, such as in parapsoriasis and poikiloderma.

Incontinentia pigmenti is a disorder of the skin arising at or soon after birth or in the early months of life, and usually in girls. It would be interesting to know how many of these subjects have been small or premature. Heilesen (1948) has stressed that there are three stages of the disorder, but that in some cases only the second stage may be present. First there is erythema with some papule or vesicle formation. Then when this subsides the affected area is noticed to be pigmented. Periodic attacks leave pigmentation more and more widely spread. In some cases the pigmentation appears in skin previously normal. The third stage—fading—may be incomplete or absent. At its height the pigmentation is found on the trunk and lower limbs in all cases. Upper limbs and scalp may be affected, as may the oral mucosa. Two cases had curious yellowish bands of pigment on the face. The colour is sometimes grey or steely blue or some shade of brown, several colours occurring in one case. The pattern is symmetrical, but often one side is more heavily involved than the other. All writers describe bizarre shapes, tree-like branching, and, round the subject's trunk, parallel lines giving a superficial and erroneous suggestion that nerves are followed.

A congenital defect of the eye or an ectodermal defect may be present in the case or in some member or members of the family. Other members of the family may have *incontinentia pigmenti*.

The familial character and the association with other recognized congenital ectodermal defects supports the view that this is a congenital abnormality of the skin.

CONGENITAL DUODENAL OBSTRUCTION AND MONGOLISM

BY

MARTIN BODIAN, M.D.

L. L. R. WHITE, M.B., B.Ch., B.Sc., D.C.H.

C. O. CARTER, B.M., M.R.C.P.

AND

J. H. LOUW, M.B., Ch.M.

(From the Department of Morbid Anatomy, The Hospital
for Sick Children, Great Ormond Street, London)

We have recently been impressed by the frequency with which intrinsic obstruction of the duodenum in the newborn has been associated with mongolism. During the past 25 years 32 infants with congenital atresia or severe stenosis of the duodenum have been admitted to Great Ormond Street, and of this number no fewer than 10 were recognized as mongols.

Case Reports

Case 1.—A first-born male child, three weeks premature. Mother aged 25. Admitted aged 6 weeks because of vomiting and constipation from birth. *Clinical diagnosis:* Mongolism and pyloric stenosis. *Operation:* Gastro-enterostomy for apparent "duodenal ileus." Death occurred a few hours after operation. *Necropsy:* Mongolism; stenosis of third part of duodenum, peritonitis, and organized pleurisy.

Case 2.—A male child, tenth in family, born at seven months' gestation. Admitted aged 2½ days with imperforate anus, severe vomiting, and deep jaundice with purpura. *Clinical diagnosis:* Mongolism with anal atresia. X-ray film suggested possible duodenal atresia. *Operation:* Relief of anal atresia. Death occurred the following day. *Necropsy:* Mongolism; atresia at junction of second and third parts of duodenum; large subarachnoid haemorrhage.

Case 3.—A full-term male child, second in family. Admitted aged 1 week with vomiting. *Clinical diagnosis:* Mongolism with duodenal atresia. Died on tenth day. *Necropsy:* Mongolism; duodenal atresia just below ampulla; partial patency of foramen ovale.

Case 4.—A male child born six weeks before term after surgical induction for hydramnios. Eighth child; mother aged 36. Admitted aged 4 days with vomiting from birth.

Clinical diagnosis: Mongolism; prematurity and duodenal atresia. Death occurred on the sixth day. *Necropsy:* Mongolism; duodenal atresia immediately above ampulla; interventricular septal defect; cerebellum disproportionately small; undescended left testicle.

Case 5.—A male child, third in family. Admitted on day of birth with progressive jaundice. Rh incompatibility; direct Coombs's test positive. Typical mongol. *Clinical diagnosis:* Haemolytic disease of the newborn with mongolism. Death took place on second day. *Necropsy:* Mongolism; severe duodenal stenosis 1 cm. above the papilla; cerebral kernicterus; erythroblastosis foetalis; Meckel's diverticulum.

Case 6.—A first-born female child, two weeks premature; white asphyxia at birth following difficult forceps delivery. Mother aged 35. Admitted aged 3 days with vomiting from birth and passage of only mucus per rectum. *Clinical diagnosis:* Intestinal obstruction. *Operation:* Duodeno-jejunosomy for atresia at duodeno-jejunal flexure; lack of mesenteric attachment of ascending colon noted. Discharged home at 1 month of age after a stormy convalescence. Recognized as a typical mongol when seen in an out-patient clinic at 5 months of age.

Case 7.—A male child, third in family. Mother aged 36; suffered from hydramnios during pregnancy. Admitted aged 7 days because of persistent vomiting. *Clinical diagnosis:* Intestinal obstruction. *Operation:* Gastro-jejunosomy for duodenal atresia. Died shortly after operation. *Necropsy:* Mongolism; complete membranous occlusion of duodenum immediately distal to ampulla; extensive peritoneal haemorrhage; small cerebellum; undescended left testicle.

Case 8.—A female child five weeks premature, fifth of family. Mother aged 40; hydramnios during pregnancy. Admitted on third day with vomiting from birth. *Clinical diagnosis:* Atresia of duodenum. *Operation:* Duodeno-jejunosomy for atresia of proximal 4 in. (10 cm.) of jejunum. Died shortly afterwards. *Necropsy:* Mongolism; duodenal atresia immediately distal to papilla; multiple atresias of proximal jejunum; small intestine much shorter than normal; universal mesentery; cerebellum disproportionately small; partial patency of foramen ovale; failure of lobation of left lung.

Case 9.—A first-born full-term female child. Mother aged 25; hydramnios during pregnancy. Infant suffered asphyxia at birth. Admitted aged 5 days with vomiting, cyanotic attacks, and purpura. *Clinical diagnosis:* Duodenal atresia and possible mongolism. *Operation:* Peritoneal bands divided. Death on eighth day with oedema and cardiac failure. *Necropsy:* Extensive peritoneal haemorrhage; duodenal atresia immediately above the papilla; mongolism, small cerebellum; large auricular septal defect (septum secundum); pulmonary oedema.

Case 10.—A male child, eighth in family. Maternal age 39; hydramnios during pregnancy. Following severe birth asphyxia the infant began to regurgitate brown fluid. Admitted aged 5 days. *Clinical diagnosis:* Mongolism and duodenal atresia. *Operation:* Gastro-jejunosomy. Deterioration after tenth day with diarrhoea; death at 3 weeks of age. *Necropsy:* Mongolism; severe duodenal stenosis immediately proximal to the ampulla; universal mesentery; small brain; aberrant right subclavian artery; umbilical sepsis; oral thrush.

Discussion

Textbooks of surgery and paediatrics do not in general refer to this association, which in our experience has occurred with remarkable frequency, nor is it mentioned in the monographs of Benda (1947) and Engler (1949) on mongolism. In a survey of published cases of duodenal obstruction in the newborn Forshall (1947) found only five instances in which associated mongolism had been observed. More recently, however, Lanman (1949), in Boston, reported that, of 17 children with duodenal

atresia successfully treated by operation, 4 were subsequently found to be mongols, while Grove and Rasmussen (1950) found 3 mongols among 11 cases of duodenal atresia or stenosis.

One of us (L.L.R.W.) recently observed mongolism in three successive infants with duodenal atresia at necropsy, in Cardiff, and from personal communications we have learned that Miss I. Forshall, in Liverpool, has seen four cases, and Miss V. Smallpeice, at Oxford, two cases.

From our observations there would appear to be a high incidence of mongolism in infants suffering from intrinsic malformations of the duodenum, the overall frequency in 25 years being approximately one in three. It is remarkable, however, that during 1951, after our interest had been drawn to the association, all five cases of duodenal atresia or stenosis admitted to Great Ormond Street have been found to be mongols; in two of these the latter condition was not recognized until post-mortem examination. Our recent experience suggests that the frequency of associated mongolism may be even higher than one in three.

A possible explanation of the paucity of recorded instances is that most uncomplicated cases of mongolism do not come under medical observation until there is obvious retardation of mental progress, at the end of infancy or later. On the other hand, most cases of duodenal atresia or stenosis die in the neonatal period at a time when the classical appearances of mongolism, though present, are not conspicuous.

The features of mongolism in newborn infants are perhaps not as widely appreciated as they might be (Carter and MacCarthy, 1951). On clinical inspection the immediate general impression is that the baby has an odd appearance. Only a careful systematic examination will elicit the presence of some of the signs of mongolism.

The head is usually rounded, and on palpation of the sagittal suture a third fontanelle may be found. The facial contour is square; the oblique palpebral fissures are small and measure less than the interocular distance; medial epicanthic folds are usually present; the nasal bridge is depressed; the ears are poorly formed and have a crumpled appearance; the tongue tends to protrude. Fingers are somewhat short and the little finger may be incurved owing to a short middle phalanx; a single transverse palmar crease is often present; the axial triradius is in an abnormal position (Penrose, 1949). A high maternal age affords further circumstantial evidence.

At post-mortem examination the most characteristic internal finding is a disproportionately small cerebellum and brain stem; associated malformations, notably cardiac septal defects, may be encountered.

It must be emphasized that no one feature is peculiar to mongolism, nor is any sign of invariable occurrence; it is the presence of a majority of these signs, however, which enables one to make the diagnosis with reasonable certainty, even in the newborn.

In view of our observations it seems important to seek evidence of mongolism in all infants with suspected duodenal obstruction, since such finding may influence the decision to operate.

Summary

In a consecutive series of 32 infants with congenital atresia or stenosis of the duodenum a high incidence of mongolism was observed.

The frequency of this association has not been generally appreciated, presumably because most children with duodenal atresia or stenosis die during the neonatal period, when mongolism is apt to be overlooked. The features of the newborn mongol are therefore reiterated. It is felt that the early recognition of mongolism in a newborn child with suspected duodenal obstruction may be of practical importance in the management of the case.

Acknowledgments are due to the clinical staff of the Hospital for Sick Children for permission to use their case records. We are also indebted to Miss I. Forshall and Miss V. Smallpeice for their personal communications.

ACUTE INFECTIOUS LYMPHOCYTOSIS

REPORT ON A GROUP OF CASES IN A DAY NURSERY

BY

H. G. DUNN, MB., M.R.C.P., D.C.H.

Late Registrar, Children's Department, the London Hospital

Acute infectious lymphocytosis was first described as a specific disease by Carl H. Smith, of New York, in 1941. It chiefly affects children below the age of 10 years, and is known to occur sporadically and also in small epidemics, particularly in institutions and among members of the same family. The literature and features of the condition were fully reviewed by Smith himself in 1947. Most of the case reports have come from North America, and the largest recorded outbreak there involved 86 persons in an institution for mentally defective and epileptic patients (Barnes *et al.*, 1949). During the last few years instances of the disease have also been reported increasingly in Europe. Thus the condition has been encountered in Finland (Klemola and Hamarinen, 1947), in Switzerland (Gsell, 1947; Landolt, 1947; Martens, 1948), in France (Debré *et al.*, 1948; Lamy, 1948; Bernard *et al.*, 1948), and in Germany (Recknagel, 1948; Koch, 1949; Heni and Zeh, 1949), as well as in Austria, Czechoslovakia, Greece, the Netherlands, Sweden, and Spain.

In this country, Kilham and Steigman (1942) first pointed out certain similarities to infectious lymphocytosis in three children whose blood showed an increase in the number of small lymphocytes and gave a negative Paul-Bunnell reaction. Later, Steigman (1946) briefly described a small outbreak affecting six children in a village in Southern England in 1942. Isolated instances of the condition in the East End of London have been reported from this hospital (Sita-Lumsden, 1947) and from Mile End Hospital (Dolphin and Popham, 1950). An account of three cases was also published in Northern Ireland (McCollum, 1949).

Six cases which appeared to originate in a day nursery in East London are described below. The first three were encountered in hospital practice.

Case 1.

A female infant, aged 1 year and 4 months was first sent to the out-patient department of the London Hospital from a local day nursery on August 4, 1950. She had always had a tendency to pass offensive loose stools with mucus, but for the previous fortnight this had been worse and she had had about seven motions daily. She was, however, still eating well and had not vomited. Her development and previous health had been normal apart from a severe attack of whooping-cough and intermittent right otorrhoea. She was the youngest of four children, and the mother reported that the others, who were all boys, were also liable to pass loose stools. The eldest had had diarrhoea for three weeks about three months previously, and the second had had it for one week a fortnight previously.

On examination the child looked healthy, and her temperature was normal. The right eardrum was hyperaemic and dull; otherwise there were no abnormal signs. The lymph nodes and spleen were not enlarged. A rectal swab revealed nothing abnormal in a film or on culture.

On treatment with dietary restriction and a kaolin mixture the stools diminished in number but remained loose and offensive. A week after her first attendance she had lost 2½ oz. (71 g.) in weight and appeared paler. The blood then showed a haemoglobin concentration of 74%* and a white-cell count of 79,400 per c.mm., with 95% lymphocytes, which were normal in appearance.

On the following day, August 12, she was admitted to hospital. She was now fretful and had a temperature of 102° F. (38.9° C.). The tonsillar lymph nodes were palpable. The fauces were slightly congested and showed some post-nasal mucous discharge. Both eardrums were hyperaemic. Otherwise she was normal.

The stools were found to contain many flagellates and cysts of *Giardia lamblia*. No pathogenic organisms were grown on repeated culture of stools and rectal swabs. Throat swabs and urine tests showed nothing abnormal, the erythrocyte sedimentation rate (Wintrobe) was 12 mm. in one hour, and a tuberculin jelly test proved negative.

Treatment consisted of intramuscular penicillin (100,000 units twice daily) and 0.5% ephedrine nose drops. The temperature declined for the first two days, then rose to 103.4° F. (39.7° C.), while a severe aphthous stomatitis developed. This appeared clinically characteristic of a

*The alkaline haematin method of estimation with photoelectric colorimetry was used throughout; 100% = 14.8 g. of haemoglobin per 100 ml.

herpetic infection; numerous small ulcers developed on the tip of the tongue and on the buccal mucous membrane, and vesicles spread on to the lips and skin outside the mouth.

The blood count on August 14 showed: haemoglobin, 65%; white cells, 80,000 per c.mm., with 91% lymphocytes. On August 19 blood was taken for Paul-Bunnell and herpes complement-fixation tests; both were negative in all dilutions. The fever appeared unaffected by penicillin, but the temperature, though swinging, declined gradually and reached normal after 12 days.

On August 22 the white-cell count had fallen to 24,500, with 72% lymphocytes. A course of mepacrine (0.05 g. twice daily for four days) was then given for the giardiasis, as well as a ferrous sulphate mixture for the anaemia. Further progress was uneventful, and the child's condition was fairly satisfactory. Three further stool tests demonstrated disappearance of the *G. lamblia* parasites.

On August 31 the blood count showed: haemoglobin, 65%; red cells, 4,060,000 per c.mm.; white cells, 11,400, with 62% lymphocytes. By September 11 the haemoglobin concentration had risen to 76%, while the white-cell count had fallen to 7,900 per c.mm., with 52% lymphocytes and 10% eosinophils. On September 27 the leucocyte count was normal (see Table I).

The complement-fixation test for herpes was repeated on August 31 and again on November 1, but remained negative. The Paul-Bunnell test was also negative again on the latter date.

Case 2

A boy aged 2 years and 5 months, the youngest brother of Case 1, also attended the nursery. He first came to the out-patient department on August 23, 1950. Like his sister, he had passed loose stools intermittently before. He had also been treated for enteritis in a fever hospital in April, 1949. He now had a cough of one week's duration, and during this time had had up to five watery motions daily.

On examination he looked healthy, and his temperature was normal. Except for the presence of post-nasal mucus in the pharynx and slight prominence of the abdomen there were no abnormal signs. A blood count showed 79,400 white cells per c.mm., of which 97% were lymphocytes; these were normal in appearance. A stool specimen contained *G. lamblia* cysts and flagellates. A course of mepacrine, 0.05 g. three times daily for five days, was prescribed, and the boy was removed from the nursery.

A week later, on August 30, the mother reported that he still passed four or five loose motions without mucus every

TABLE I.—White Blood Cell and Differential Counts, of Affected Children

Case No.	Date (1950)	Total Count per c.mm.	Lymphocytes % (total per c.mm.)	Eosinophils % (total per c.mm.)	Neutrophils %	Monocytes %	Basophils %

day. He had also developed a cold, but was eating well. There were no new signs except those of coryza. The blood count showed: haemoglobin, 86%; leucocytes, 61,000 per c.mm., with 91% lymphocytes and 2% eosinophils. A specimen of stool and a rectal swab revealed no abnormality on film or culture.

During the following week the motions became normal again and the boy began to gain weight. On September 6 the haemoglobin concentration had fallen to 74% and the white-cell count to 19,600 per c.mm., of which 69% were lymphocytes and 8% eosinophils. The stool was again normal on film and culture. A week later the white cells had diminished further to 10,200, and the differential count was normal (see Table I). A Paul-Bunnell test on October 11 showed heterophil antibodies within normal limits (up to a titre of 1:10).

The two elder brothers were also examined. The first was a schoolboy 5½ years old. He also had occasional diarrhoea, but repeated stool examination showed nothing pathological, and his blood count was normal on two occasions. The second brother, aged 3½ years, attended the same day nursery as the two younger children. He was seen on August 23, when he had diarrhoea and signs of bronchiolitis; he was found to pass *G. lamblia* flagellates and cysts in his stool, and his white blood count was 14,300 per c.mm., of which 55% were polymorphonuclear neutrophils and only 42% lymphocytes. He was given a course of mepacrine, 0.05 g. three times daily for five days, and the diarrhoea subsided after a week. Three further stool tests were then negative for *G. lamblia*. On September 16 he was quite well; the blood count showed a haemoglobin content of 74% and 19,800 leucocytes per c.mm., with 53% lymphocytes and 10% eosinophils. Subsequently the white-cell count fell to normal levels. In October he had some loose stools again, and a specimen once more revealed a few *G. lamblia* flagellates.

The mother of these children had no diarrhoea. Her blood count and stool examination were normal.

Case 3

A baby girl attended the same day nursery as the children described previously. In June, 1949, she had had bacillary dysentery of the Flexner type and had been treated with sulphaguanidine. After that she continued to pass five or six relaxed stools daily, and because of this she had been seen at the out-patient department in November, 1949, when she was 17 months old. Stool examination then revealed the presence of many cysts of *G. lamblia*. She was given mepacrine, 0.05 g. twice daily for 10 days. Subsequently her motions were normal until February, 1950, when she started having intermittent diarrhoea again. Stool and rectal swab examinations were normal in February and March, but on May 5 many *G. lamblia* cysts were again present in the stool. After another course of mepacrine, 0.05 g. twice daily for five days, the stools became normal. In August she was brought up again because of mild diarrhoea. Two rectal swabs and two stool tests showed nothing abnormal, but a blood count on August 30 demonstrated a haemoglobin concentration of 79% and a leucocytosis of 40,000 cells per c.mm. with 88% lymphocytes. At that time she had coryza and a cough, but the fauces appeared normal, and lymph nodes and spleen were not enlarged. Unfortunately, she then ceased to attend the hospital and was not brought to the nursery again until mid-October. On October 20 she was examined there and appeared healthy. The jugular lymph nodes were palpable; the fauces were slightly injected, and the abdomen was rather prominent. The white-cell count was now 10,400 per c.mm., with 74% lymphocytes.

Investigations at the Nursery

Thus *G. lamblia* infestation was known to be present in four, and lymphocytosis, presumably of the acute

infectious type, in at least three children attending this particular nursery. It was decided to make further investigations there in order to determine the incidence of the two conditions.

The nursery is a fairly spacious and modern building in one of the back streets of Whitechapel. At the time of the inquiry there were 53 children in daily attendance from Monday to Friday.

It would have been most interesting to carry out weekly clinical examinations, blood counts, and stool tests on all the children and their adult attendants in the nursery. But, as time and laboratory facilities were limited, it was decided to deal with not more than six persons on any one day and to go through the whole nursery population in that manner. Blood counts and stool tests were only repeated in those in whom clinical or laboratory findings suggested some abnormality.

Between September 11 and October 26 all the children at the nursery were examined personally, and at least one blood count and stool test were performed on each of them. Blood samples were also taken from the 22 adults who were working there; only eight stools were obtained from these. It may be stated at once that nothing abnormal was found in the individual tests on the adults.

Nine children were shown to pass *G. lamblia* cysts in their stools. With the members of the family of Cases 1 and 2 this adds up to 12 infested children out of 53. The real incidence may be assumed to have been considerably higher, as it is well known that *G. lamblia* may be found only after repeated testing of stools and that one examination per case will discover only from one-third to one-half of the actual number of infections (see Boeck, 1927). Moreover, the faeces were examined by inspection of wet films in saline and not by concentration methods.

The blood counts revealed only one further definite and one probable case of lymphocytosis. Adding the previous patients, this gives a total of 5 out of 53 children in the nursery.

Case 4

A boy aged 3 years had been perfectly well without complaints of any kind. On examination on September 22 he appeared healthy, and his rectal temperature was normal. There were no abnormal signs; his lymph nodes and spleen were not enlarged. Surprisingly, his white-cell count was 42,700 per c.mm., of which 91% were normal lymphocytes and 3% eosinophils. His stool on that day contained many cysts of *G. lamblia*.

On September 28 the leucocytosis was reduced to 31,800 per c.mm., with 85% lymphocytes and 4% eosinophils. After another three weeks the count had returned to normal levels at 10,100 per c.mm., of which only 42% were lymphocytes, but still 5% eosinophils. A Paul-Bunnell test was negative. Like the other children with giardiasis he was given a course of mepacrine, and three subsequent stools were free of parasites. In December he was admitted to hospital suffering from concussion and fracture of the left tibia after an accident. His blood count then showed a haemoglobin concentration of 70%, white cells 10,000, with only 20% lymphocytes and 3% eosinophils (see Table I).

Case 5

A girl aged 3 years and 4 months, who had been free of symptoms, was first examined on September 19; and appeared healthy. Her rectal temperature was normal. The only abnormal signs were the presence of post-nasal muco-

pus and of palpable jugular and right posterior cervical lymph nodes. Her blood count showed 14,800 white cells with 79% lymphocytes. Her stool specimen on October 2 contained many cysts of *G. lamblia*.

She remained well and was given a course of mepacrine. As the initial lymphocyte count was high, further samples of blood were examined at intervals. On October 5 this showed 15,300 leucocytes per c.mm., of which 78% were lymphocytes. By October 19 the total count had risen to 23,800, still with 78% lymphocytes. A week later it had fallen to 11,000, with 66% lymphocytes. The stool was free of parasites on October 24.

This girl thus had an absolute lymphocytosis reaching three times the maximal normal value, which according to Smith (1941) should be about 6,000 lymphocytes per c.mm. at this age. It may be argued that she had a non-specific lymphocytosis due to upper respiratory tract infection, but against this it should be pointed out that the increase in the number of lymphocytes was more marked than in that condition (see Smith, 1941) and ceased fairly suddenly.

The other 47 children showed no gross clinical abnormality, but some evidence of upper respiratory tract infection was found in no fewer than 17. The leucocyte counts varied from 5,200 to 21,100 per c.mm. with an average of 11,200, and are arranged according to age groups in Table II, together with those of the adults. Whenever a child had more than one count, only the first has here been used for calculation, in order to avoid weighting the averages in favour of high values.

TABLE II.—Other White-cell and Lymphocyte Counts in the Nursery

Age	No. of Persons	Average Total White-cell Count per c.mm.	Average Total Lymphocyte Count per c.mm.	Corresponding Lymphocyte Percentage
3 months-1 year	4	12,875	8,686	67.5
1-2 years	12	12,008	7,297	60.8
2-3 "	15	10,513	6,253	59.5
3-4 "	9	10,700	5,757	53.8
4-5 "	7	10,971	5,377	49.0
All children	47	11,200	6,523	58.2
Adults	22	9,014	3,402	37.7

Kato (1935) found in a large series of normal American children that the average white-cell count gradually fell from 11,000 per c.mm. at the age of 3 months to about 7,500 at 9 years, and that the average absolute lymphocyte count declined from over 6,000 in the second month of life to the adult level of 2,500 at 15 years, being equalled by the granulocyte count at 4,000 per c.mm. at the age of 4 years. Again, Smith (1941) states that the maximal normal absolute number of lymphocytes drops from approximately 7,000 per c.mm. at 1 or 2 years of age to 6,000 at 3 or 4 years, and finally to 5,000 at puberty, while the maximal normal lymphocyte percentage is about 60 between 6 months and 2 years of age and 50 by the end of the sixth year.

A variety of normal values are given in textbooks, but at least in comparison with these American data the average total white-cell and absolute and relative lymphocyte counts will be seen to have been high in the nursery. Therefore it would seem quite likely that there were some more cases of infectious lymphocytosis with only slight blood changes. However, many mild infections will cause a slight absolute lymphocytosis in children, and thus I have thought it best not to label any case as acute infectious lymphocytosis unless the absolute

lymphocyte count exceeded twice Smith's maximal normal value for the age concerned. Only the patients described so far satisfied this criterion.

I thought it would be interesting to investigate the family of Case 4 in order to see whether any other members had lymphocytosis or giardiasis. This boy had an elder sister and a 6-year-old brother who were school-children. The mother was asked to bring them to the nursery to be examined. She herself had a normal white cell and differential count; the brother's counts were also normal on three occasions and his stool was free of parasites; but the sister (Case 6) had lymphocytosis.

Case 6

A girl aged 7 years was first seen on October 6. She had had intermittent frontal headaches for a few months, and her appetite had been only moderately good. She had also complained of toothache and right earache for one week, and had had several carious teeth extracted on the morning of the day when I first saw her.

On examination she was pallid but well nourished. Her tonsils and jugular lymph nodes were slightly enlarged. Otherwise, apart from the tooth sockets containing fresh blood clots, there were no abnormal findings. The first blood count was performed on October 12. It showed 50,400 white cells per c.mm., with 84% lymphocytes, which were normal in appearance. On October 20 the white-cell count had fallen to 40,800, of which 70% were lymphocytes and 4% eosinophils. On the same day the Paul-Bunnell test was negative. The girl was not seen again until November 7, when the white-cell count had returned to normal; her stool then contained no parasites. She was well during the whole of this period. One further stool test proved normal.

Discussion

These six cases satisfy all the criteria of acute infectious lymphocytosis (Smith, 1941)—namely, marked leucocytosis with absolute lymphocytosis; benign clinical course; absence of splenomegaly and of significant lymphadenopathy; negative Paul-Bunnell test; and no manifestations of infectious mononucleosis or of leukaemia—lymphocytes of small normal mature type.

Epidemiology.—As regards the epidemiology of the disease, the present experience confirms that its infectivity generally tends to be low. Reyersbach and Lenert (1941) encountered only 16 cases during six months in an institution housing 108 children; I found only five on mostly single blood estimations in the course of about two and a half months in a day nursery with 53 children. However, in some reports the condition has affected a higher proportion of children in more epidemic form (Finucane and Philips, 1944; Barnes *et al.*, 1949). It is also possible that some of the contacts may be infected without developing fully characteristic blood changes; this may have happened, for instance, in the second brother of Case 1. The incidence among members of the same family has been observed before (Smith, 1944; Moyer and Fisher, 1950) and is well illustrated by the present cases.

Incubation Period.—This has been estimated as being between 12 and 21 days (Smith, 1944); in one of the cases of Barnes *et al.* (1949) it appeared to be 16 days. It may be assumed that my Case 6 acquired the infection from her brother (Case 4), who attended the nursery, and it is interesting that their lymphocyte counts, while falling, reached roughly similar levels at an interval of just over three weeks. It is less safe to assume that Case

2 was infected by his sister (Case 1), as both attended the nursery; in these, the corresponding interval was just below two weeks. If these intervals are any guide to the incubation period, it would agree fairly well with the suggestions made by the observers quoted above.

Symptomatology.—The symptomatology in these patients was similar to that of previously recorded cases. In a considerable proportion there may be no symptoms at all, and the condition may be discovered only on blood examination; this occurred in two of my six cases. Of the possible clinical features, fever is said to be present in some cases at the onset. It was found in only the first of these patients, but here it was severe, as in Duncan's (1943) case. Abdominal symptoms are not infrequent and may even simulate an acute surgical condition; the commonest complaint is diarrhoea, which may occur in mildly epidemic form (Peterman *et al.*, 1949), and this was present in three out of the six cases described here. Perhaps it is more likely to occur in those with previously abnormal bowel function, for in all three patients with this symptom there was a past history of loose stools, and *G. lamblia* infestation may have played a part. Mild upper respiratory infection is common in this disease: some evidence of it was found in five of these six patients. Symptoms or signs of meningeal irritation have been reported in occasional cases, but were not evident in the present ones. As regards skin manifestations, it is of interest that Smith (1944) observed a herpetic eruption on the face of a child at the onset of the disease. In my first case the aphthous stomatitis and vesicles on the lips strongly resembled herpetic lesions; yet the complement-fixation test for herpes was repeatedly negative. One wonders whether acute infectious lymphocytosis should be remembered as a possible cause of apparent herpetic eruptions and also whether a virus might be cultured from these vesicles in lymphocytosis.

Haematological Findings.—These correspond to those observed elsewhere. In five of my six cases the maximal total white-cell counts exceeded 40,000 per c.mm. The highest proportion of lymphocytes varied between 79 and 97%. The lymphocytes were normal in size and structure, and thus differed from those usually found in glandular fever. The total duration of the abnormal lymphocyte levels could not be estimated, as no observations were made while these were rising from normal. The periods of fall lasted two to four weeks, and this agrees approximately with Finucane and Philips's (1944) observation that the leucocytosis lasted from two and a half to seven weeks, with an average probable duration of about five weeks.

An absolute eosinophilia has been observed by several previous authors (Finucane and Philips, 1944; Landolt, 1947; Barnes *et al.*, 1949). The figure of 400 per c.mm., which is often given as the upper limit of normal (Whitby and Britton, 1950), was exceeded in all my six cases, and at least five of them had more than 790. In two of them the maximum eosinophilia occurred after the peak of the lymphocytosis. Monocytes were often absent at the height of the disease and reappeared towards the end as they do in other acute infections. The platelets were always plentiful in the films.

Differential Diagnosis.—In arriving at a diagnosis several diseases had to be considered. Glandular fever first came to mind, but there was no splenomegaly and little lymph-node enlargement, which was confined to the neck; also, the leucocyte count showed a greater

increase, the lymphocytes were normal in type, and the Paul-Bunnell test was negative in four cases. Leukaemia was ruled out by the benign course, and by the absence of lymphadenopathy, of abnormal blood cells, and of thrombocytopenia. There was no clinical evidence to support the possibility of whooping-cough. Chronic non-specific lymphocytosis of the type which may accompany and follow upper respiratory or other infections was unlikely to be the cause as the leucocyte response was too marked and short in duration.

Possible Relationship to *G. lamblia* Infestation.—Finally, this question has to be discussed. The total incidence of giardiasis in 12 out of the 53 children at the nursery, as determined by mostly single stool tests, is probably within the usual limits, for Boeck (1927) found that the incidence in children reported in the literature varied from 14 to 40%, and it is known to be even higher in residential institutions (Brown, 1948). There is still no agreement concerning the pathogenicity of these parasites, but they can probably be responsible for malabsorption (Véghelyi, 1940) and may sometimes cause enteritis (Miller, 1926; Ormiston *et al.*, 1942). Among my 12 cases of known *G. lamblia* infestation it was noteworthy that 7 had a history of diarrhoea within the last month, whereas only 5 out of 40 children without parasites in their stools had had this experience. However, it must also be remembered that diarrhoea by itself may wash *G. lamblia* flagellates down from the duodenum and jejunum, which are their habitat. It is interesting that the 12 children in this series who are known to have harboured the parasites included five out of the six cases with lymphocytosis, and that at least four of these six were passing *G. lamblia* at the time of the disease; but there is no proof of any definite association, and this will have to be a matter for future investigation.

Summary

Six cases of acute infectious lymphocytosis are recorded. The patients were children whose ages ranged from 16 months to 7 years. Five of these attended a day nursery in the East End of London, and the sixth was the elder sister of one of the others.

The constitutional symptoms were fairly severe in the youngest child, who had marked fever and aphthous stomatitis; the latter resembled a herpetic infection clinically, but was not associated with a positive complement-fixation reaction to herpes simplex. The other cases were mild, and at least two patients had no symptoms attributable to the condition.

Four of the six children were found to pass *G. lamblia* flagellates or cysts in their stools, and a fifth had received two courses of treatment for this infestation during the previous year.

Three of the patients attended the out-patient department of a hospital because of diarrhoea. The others were found on the basis of mostly single blood counts performed on the remaining 50 children attending the nursery and on 23 adult and two child contacts in the course of about six weeks. Single stool tests, performed simultaneously, showed that a total of 12 out of the 53 nursery children harboured *G. lamblia* parasites.

The epidemiology, clinical features, blood changes, and differential diagnosis of acute infectious lymphocytosis are briefly discussed in relation to the cases described.

I wish to thank Dr. R. H. Dobbs for his encouragement and for permission to publish the first three cases. My thanks are also due to the Divisional Health Officer of the London County Council for permission to make investigations at the nursery. I am grateful to Professor S. P. Bedson for performing the herpes

complement-fixation tests, to Dr. H. B. May and his staff for the other laboratory investigations, and to Dr. K. H. Tallerman and Dr. F. W. Nash for help and criticism.

TUBERCULOUS MENINGITIS

TREATMENT WITH STREPTOMYCIN AND
PARA-AMINOSALICYLIC ACID

BY

S. RUSSELL JAMIESON, M.D., D.P.H.

Medical Superintendent, Castle Hill Hospital,
Cottingham, East Yorkshire

An apparent cure, without sequelae, can be expected in 50% of cases of tuberculous meningitis treated by streptomycin, and, provided skilful treatment is given early in the disease, a higher percentage can make a complete recovery. In an attempt to increase the recovery rate by using para-aminosalicylic acid (P.A.S.) in combination with streptomycin 35 cases of tuberculous meningitis were treated and reviewed at Castle Hill Hospital.

On admission all cases were classified as: (1) Early case (E)—fully conscious patient, with no focal signs, slight nuchal rigidity but with abnormal cerebrospinal fluid. (2) Middle case (M)—fully conscious, but sometimes drowsy and lethargic, with nuchal rigidity and focal signs. (3) Advanced case (A)—unconscious or deeply stuporous patients.

The diagnosis was confirmed by isolation of the tubercle bacillus from the cerebrospinal fluid in 30 cases. The five in which tubercle bacilli were absent showed other specific signs and symptoms of the disease.

The results of treatment were assessed after a minimum survival period of one year from the date of admission, and cases were observed for up to 30 months.

Treatment

All cases were given a six-months' course of intramuscular and intrathecal streptomycin combined with oral P.A.S. The daily dose of intramuscular streptomycin was 1 g. and was given to all patients in two twelve-hourly doses of 0.5 g. The daily dose of intrathecal streptomycin was 100 mg. for patients of 5 years and over, and 50 mg. for those under 5 years. Oral P.A.S. was given in gradually increasing dosage as follows: 3 g. for patients 12 years or over, 1.5 g. for those 5–11 years, and 0.75 g. for those 1–4 years—1 dose daily for three days, then 2, 3, 4, 5, and 6 doses each for three days, so that at the end of 18 days each patient was receiving six doses a day at intervals of two-and-a-half hours, from 9 a.m. to 9.30 p.m. The tendency to nausea and vomiting was much reduced if the patient ate something before a dose—for example, a few biscuits and milk. An alkaline mixture given before a dose may help in preventing nausea, and a chalk-and-opium mixture may be given for the treatment of diarrhoea. However, with the above dosage these symptoms were rarely met with. P.A.S. was given continuously throughout the patients' stay in hospital in the recommended dosage. On discharge it was continued as a bacteriostatic agent at a reduced dosage throughout the period of observation.

Treatment was given for six days a week, Sunday being a complete rest period. All patients were kept in bed for the six-months course of streptomycin treatment. A radiograph of the lungs was taken and full chemical and bacteriological examinations of the cerebrospinal fluid (C.S.F.) were made monthly. Patients were not allowed up until the C.S.F. was normal, and they were kept in hospital for at least one year.

Diagnosis

In the known tuberculous child with obscure symptoms, spread to the meninges must always be considered; the incidence of meningitis is highest in the first three months after the development of the primary lung lesion. Children exposed to tuberculosis at home must be kept under observation for the beginning of a primary lung lesion and for subsequent spread to the nervous system. The signs and symptoms of tuberculous meningitis are varied, but most cases conform to a general pattern. Rarely the onset is sudden, with focal signs in the nervous system such as convulsions, cranial nerve paralysis, and limb paralyses. More often the meningitis begins insidiously, with symptoms which may at first mimic minor ailments.

The disease tends to be most treacherous in infancy and early childhood, with a more vague onset and more rapid progress than is usual in the older patient. In older children listlessness and irritability may be the first symptoms: an otherwise good-natured and happy child loses interest in his toys and quarrels with his playmates. The parent may remark that he is easily tired and that he falls asleep in a chair or at meal-times. Headache is a common complaint of older children in the early stage, and vomiting may occur.

History of Contact.—A definite history of contact with diagnosed tuberculosis in the home was found in 14 of the 35 cases.

Mantoux Test.—This test is a highly significant aid to diagnosis, particularly in young children. Reliance should not be placed on the tuberculin patch or jelly test performed during the course of meningitis, because the allergic response to tuberculin is commonly reduced in these cases, so that a negative result is obtained. A properly performed Mantoux test, using fresh material and a 1 in 100 solution if the 1 in 1,000 is negative, is positive in over 90% of cases. The Mantoux test was performed in all cases. The reactions are shown in Table I.

TABLE I

	E Cases	M Cases	A Cases	Total
Positive at 1 in 10,000	2	5	2	9
" " 1 in 1,000	0	8	17	25
" " 1 in 100	0	0	1	1
Negative in all three dilutions	0	0	0	0

Radiography.—Routine chest radiography proved another valuable aid. Definite abnormalities in the chest x-ray film were seen in 23 of the 35 cases. (Two patients died before radiographs could be taken.) They comprised (a) a primary complex (usually hilar adenitis with a pulmonary focus) in 14 cases; (b) miliary disease of the lungs in seven cases; and (c) phthisis present in two adults. In the remaining 10 cases no abnormality was seen.

C.S.F. Examination.—The general appearance of the C.S.F., cell count, protein content, chlorides, and sugar were estimated monthly along with direct examination for tubercle bacilli and culture on Lowenstein's medium. For the initial diagnosis as many as 12 daily C.S.F. examinations were done. If a Mantoux-positive case with no tubercle bacilli on direct examination showed a lymphocytosis with increased protein and lowered sugar and chloride content on two occasions, treatment was begun without further delay. These cases were nursed in isolation until their C.S.F. cultures showed tubercle bacilli; they were then transferred to the tuberculous meningitis ward. Cases of tuberculous meningitis with positive sputum were nursed in isolation during their 12 months' stay in hospital. Thirty cases showed tubercle bacilli in the C.S.F. Of the five remaining cases, one was proved post mortem to have tuberculous meningitis and four were Mantoux-positive, and their C.S.F. showed a lymphocytosis with increased protein and lowered sugar and chlorides on more than two occasions. Other causes of a lymphocytosis in the C.S.F. which require to be considered in the differential diagnosis are: polio-encephalitis and poliomyelitis; benign lymphocytic choriomeningitis; glandular fever; mumps encephalitis; spirochaetal infections (syphilis, leptospiral diseases, relapsing fever); infective hepatitis; atypical pneumonia; herpes zoster; psittacosis; trypanosomiasis; and yeast meningitis.

Results

Of the 35 patients treated, 28 survived and 7 died. Of the 28 survivors 26 have normal C.S.F.; 19 are clinically fit and well, and of the remaining nine three are fit and well except for partial deafness, audiograms showing loss of hearing of 10–40 decibels. These cases

are being fitted with hearing-aids and their progress is under observation. The six remaining cases showed the following features.

Case 10.—A woman, aged 20, on admission was six months pregnant, was comatose, and had right hemiplegia. She was given combined treatment, and caesarean section was done at the 38th week of pregnancy. The baby was born alive, but died after 48 hours. At the end of 581 days the patient was fit and well and showed only slight paresis of the right leg; she could walk and do her ordinary housework with the aid of a calliper splint on that leg. The C.S.F. on the 581st day was normal.

Case 13.—A boy, aged 3, on admission had tuberculous meningitis, miliary tuberculosis of lungs, and tuberculosis of the right ankle, which broke down and discharged freely. On the 850th day he was fit and well, but the C.S.F. showed a lowered sugar content. He wears a calliper splint for the right ankle condition, which has healed.

Case 15.—A boy aged 1 year. On the 584th day of observation he was well nourished and the C.S.F. was normal, but he was mentally retarded. Since discharge from hospital his guardian states that he has greatly improved and is now able to walk, but he will require psychometric assessment at a later date.

Case 25.—A boy, aged 23 months, was comatose and blind on admission. On the 639th day of observation he could see, walk, and run, and was attempting to talk. He was also partially deaf and mentally retarded, and will require psychometric assessment at a later date.

Case 28.—A girl aged 14 completed a full course of treatment and was discharged home after one year in hospital. Six months later she was readmitted with miliary tuberculosis of the lungs and given a three-months course of 1 g. daily of dihydrostreptomycin and P.A.S. At the end of six months she was much improved: monthly examinations showed the C.S.F. to be normal.

Case 29.—A female infant aged 9 months. In the second week of treatment she had a convulsion with a residual spastic paresis of the left arm and leg. On the 644th day of observation she was much improved and could walk and run; only slight spasticity of the left arm remained. She was partially deaf and slightly retarded mentally, and was given one "cytacon" tablet daily (10 mg. of vitamin B₁₂), with beneficial effect: she is now much more active and alert, and is attempting to talk.

Table II shows the details of the 35 cases.

Discussion

During streptomycin-P.A.S. treatment rashes, fever, loss of weight, anorexia, vomiting, vertigo, deafness, and albuminuria occur in varying degrees. With the exception of deafness most of these symptoms subside when the streptomycin is stopped. The rashes usually respond to antihistamine drugs; these substances have also been used by various authorities for the treatment of vertigo and deafness, but definite conclusions have not yet been reached.

Marked degrees of hearing loss and partial deafness form the one serious complication which occurs in cases otherwise fit and well. Although the evidence is at present conflicting, it would certainly seem that the auditory nerve as well as the vestibular nerve is affected in some cases, and the general consensus is that the neurotoxic streptomycin may be responsible. Whilst it is impossible to say that the severe degree of deafness will be permanent, the rate of recovery is extremely slow and the education of the affected children would certainly suffer without special educational treatment. This is particularly so with very young

children whose early appreciation of speech has been insufficient to give them any permanent memory of sound.

Some authorities believe that the deafness is due to the tuberculous process and support this by the fact that streptomycin has been extensively used for other forms of tuberculous disease and, whilst admitting damage to the balancing mechanism in the inner ear, affirm that it is not a cause of deafness when used in the normal dosage.

The occurrence of deafness in cases of tuberculous meningitis treated with streptomycin shows considerable variation in incidence from place to place, and in order to obtain reliable statistics it would be necessary to do objective tests of hearing in all cases, otherwise cases of high-frequency deafness might easily be missed.

As regards the mental impairment following tuberculous meningitis, it is difficult to assess in some cases owing to motor disability and poor hand-eye co-ordination. Objective assessment as compared with pre-illness history would indicate some impairment of intellectual functioning in certain cases, but repeated follow-up examinations are necessary to ascertain whether this is likely to be permanent.

The marked increase in weight in marasmic babies after intramuscular injections of vitamin B₁₂ was noted and it was decided to give all cases of tuberculous meningitis showing muscular wasting one tablet of

cytacon daily. In addition to increased weight gain (Table III) patients also showed increased activity and alertness and definite increase in appetite.

Various writers on the treatment of tuberculous meningitis have stressed the disturbing and severe strain on the nursing staff attending these cases, but in this hospital the daily lumbar puncture for six months is accepted by patients and staff as a normal routine procedure. Apart from the actual lumbar puncture session, the tuberculous meningitis ward is one of the most cheerful wards in the hospital. This is all due to the extremely kind and efficient methods of the matron, Miss D. H. Dronfield, and her nursing staff, and their own inward satisfaction at seeing results impressive for a disease which until the last few years was usually fatal.

CHLORAMPHENICOL IN TREATMENT OF CUTANEOUS ANTHRAX

BY

P. S. CLARKE, M.B., B.S., L.M.S.S.A.

Chief Medical Officer, Tingri Medical Association

Chloramphenicol in concentrations of 5 µg./ml. has been shown to inhibit *in vitro* several strains of *Bacillus anthracis*, one strain being rather more susceptible (McLean, Schwab, Hillegas, Schlingman, 1949). Its clinical effect was therefore tried on four cases of cutaneous anthrax in Indian labourers.

Case 1

An Indian labourer was admitted to hospital on June 7, 1950, in a restless comatose condition. His temperature was 96° F. (35.6° C.), pulse 74, and respirations 30. The spleen was palpable. On examination the pulmonary condition was normal. A blood slide showed the presence of malaria parasites. Kernig's sign was positive and neck rigidity was present. There was a vesicular pustular eruption with an oedematous base over the proximal end of the left fibula. A smear from this sore showed *B. anthracis* ++. He was treated with "acetylarsan," 3 ml. intramuscularly, and procaine penicillin in oil, 300,000 units. Sustaining measures and lumbar punctures were impossible owing to his restlessness, and he died seven hours after admission. Post-mortem examination was refused. A provisional diagnosis of anthrax meningitis, with possibly intestinal anthrax, was made.

Immediate inquiries elicited that a cow had died under suspicious circumstances seven days previously, and that he, with about 50 others, had cut it up and eaten it. All these contacts were immediately examined, and four further cases of anthrax were discovered. All belonged to the scavenger class.

Case 2

A man aged 35 was admitted at 7 p.m. on June 7. There was a history of carving and eating the same cow. His temperature was 100° F. (37.8° C.), pulse 100, and respirations 28. He was anaemic, and his heart was slightly enlarged (a usual condition in these people). There was a sore on the left thumb $\frac{1}{2}$ in. (1.25 cm.) in diameter which had been present for a week. It had started, after some itching, as a circular red papule; it had then become vesiculated and a dark scab had formed in the centre. By this time the base was very oedematous and the whole sore steadily grew bigger, the scab softening and becoming a dirty colour rather than black; a number of surrounding vesicles became confluent and exuded serum. The regional lymph nodes were not enlarged or tender. There was a second oval sore $2\frac{1}{2}$ in. (6.3 cm.) long on his back, and a third on the lateral aspect of the left knee. Slides from all three sores showed a heavy infection of anthrax.

He was treated on traditional lines with procaine penicillin in oil, 300,000 units daily for seven days. Sulphadiazine was given as follows: 3 g. immediately, 1 g. four-hourly for three days, and 1 g. thrice daily on the fourth day. Acetylarsan, 3 ml., was given on the first day and neoarsphenamine, 0.3 g., on the second day. Neoarsphenamine, 0.15 g., was given on the fourth and eighth days. The temperature and pulse settled to normal by the fourth day, and all sores had diminished in size; oedema was much less. The cultures remained positive until the ninth day and were thereafter negative. All sores were healed on the twenty-fifth day.

Case 3

A girl aged 12 was admitted on June 7 with a sore over the insertion of the left deltoid. She had eaten some of

the same cow, and her brother (Case 4) was also affected. The sore had started with an itching place, and a circular red papule soon appeared. On June 4 this had grown and become vesicular. On her admission there was a depressed black scab at the centre surrounded by a confluent unbroken vesicle $\frac{1}{2}$ in. (1.25 cm.) in diameter, the whole lying on an oedematous base. One secondary papule was present immediately outside the ring of vesicles. Her temperature was 100° F. (37.8° C.), pulse 104, and respirations 39. The regional lymph nodes were enlarged and tender. A slide showed *B. anthracis* +.

Chloramphenicol, 1.75 g. (60 mg. per kg. of body weight) orally, divided into four doses given every hour, was administered that night, and 750 mg. (26 mg./kg.) thrice daily was started next day and continued for three days. The doses were then reduced to half this amount for a further three days. Pulse and temperature were normal by the fourth day, and the sore had dried up; oedema had disappeared and the slide was negative for anthrax. On the thirteenth day the lymph nodes had entirely subsided and the scab separated, and slide and culture were negative for *B. anthracis*. All sores were completely healed on the twenty-third day.

Case 4

A boy aged 10 was admitted on June 7 with a history identical to that of his sister (Case 3). On admission he had a sore measuring $1\frac{1}{2}$ by $1\frac{1}{2}$ in. (3.2 by 4.4 cm.) on the back of his knee. In the centre there was a dark tough scab which was surrounded by a vesicle that had burst. The base was grossly oedematous. The regional glands were enlarged and tender. His temperature was 100° F. (37.8° C.), pulse 108, and respirations 32. A slide showed *B. anthracis* +.

Chloramphenicol, 1.25 g. (52 mg./kg.) divided into four doses, was given at hourly intervals, and from next morning 620 mg. (26 mg./kg.) thrice daily was given for three days, and then the dose was halved for two days and finally reduced to 60 mg. thrice daily for three days. The temperature had settled by the second day, and on the third day the slide was negative. By the fourth day there was much less oedema, and the sore was cleaner. On the eighth day a culture gave a positive result, but thereafter eight daily cultures were negative. He made an uneventful recovery, and all sores were completely healed on the twenty-ninth day.

Case 5

An infant aged 10 months was admitted on June 7. There was no history of eating or handling affected meat. Case 2 stated that after he had cut off his portion from the cow and taken it home he had taken the infant on his knee and played with it. The mother, who had cooked and eaten the meat and had nursed the child at the breast throughout the whole illness, was not affected. Four sores were present—two on the abdomen each 1 in. (2.5 cm.) in diameter, one on the right forearm $\frac{1}{2}$ in. (1.25 cm.) in diameter (see illustration), and a small sore starting on the

Case 5. Showing two sores on abdomen and one on right forearm.

leg. The temperature was 100° F. (37.8° C.), pulse 150, and respirations 50. A slide showed *B. anthracis* +.

Chloramphenicol, 0.375 g. (64 mg./kg.), was given in powder form followed immediately by breast-feeding. No further dose was given that night. From next morning 188 mg. (32 mg./kg.) thrice daily was given for 60 hours; then the dose was reduced by half for a further 60 hours and again halved for a further 48 hours. On the second day the temperature was 102° F. (38.9° C.), pulse 160, and respirations 50. The sores and the general condition were the same. A slide showed *B. anthracis* ++. Next day the general condition was the same except for mild diarrhoea. The sore on the leg had not increased in size, but a vesicle had formed and burst. A slide showed *B. anthracis* +. On the fourth day the general condition was good, the diarrhoea less, all sores were slightly smaller, and the leg sore was drier. The dark-scabs were more pronounced. On the fifth day the general condition was good, stools were normal, and the sores dry. A negative slide but positive culture were found on the eighth day by lifting the scab and culturing the underlying pus. Thereafter the sores gradually healed. All further slides were negative, but a further positive culture was obtained on the thirteenth day. Cultures on the ninth, tenth, fourteenth, and fifteenth days were negative. A peculiarity of this case was the persistently oedematous base, which only gradually subsided, whereas in the other cases oedema disappeared rapidly. After some secondary infection the sores were completely healed on the thirty-ninth day.

Case 6

A man aged 55 was admitted to hospital on July 8 with a sore on his back and with fever. This was an isolated case occurring in a different district in a member of a different caste. On July 3 he had felt an itching on his back and rubbed it. He then noticed a lump and a vesicular sore on his back. This gradually enlarged, and on July 5 he felt feverish. There was no history of how the infection could have occurred. On admission a malignant pustule was seen on his back about 3 in. (7.5 cm.) above the right iliac crest, in the same position as one of the sores in Case 2, and presumably caused by carrying infected meat on the back. The sore measured 1½ by 1½ in. (4.4 by 3.8 cm.) and had a black centre surrounded by ruptured vesicles exuding serum. The skin surrounding the sore was oedematous for about 12 in. (30 cm.) and for a rather greater distance downwards and over the abdominal wall. The right axillary glands were enlarged and tender. The spleen was not palpable. His temperature was 101.4° F. (38.6° C.), pulse 90, and respirations 28. His weight was 112 lb. (50.9 kg.). A slide was negative for *B. anthracis*, but culture was positive.

Treatment was not given on July 9 owing to administrative difficulties. On July 10 chloramphenicol, 3.25 g. (64 mg./kg.) divided into four doses was given every hour. Nothing further was given that night. On July 11, 12, and 13, 1.5 g. (29.6 mg./kg.) was given thrice daily. The dose was halved on July 14 and 15. On July 10 his temperature was 101.4° F. (38.6° C.), pulse 80, and respirations 20. The sore looked slightly bigger and had an angry-looking edge with increased serous discharge. The pain and irritation were more marked. The oedema had spread round to the nipple and was more pronounced. Regional lymphadenitis was increased. A slide was negative for *B. anthracis*, but culture was positive. Next day, 12 hours after starting treatment, there was a dramatic improvement: the sore was the same size, but there was no pain or itching, the serous discharge was less, the central slough rather bigger, and oedema had definitely diminished in area and severity. Regional lymph nodes were smaller and not tender. On July 12 further rapid improvement occurred. A slide and culture were negative. All further slides and cultures were negative. On July 13 there was no oedema. The whole sore was dry and covered by a black scab.

The patient was discharged on July 19 to the out-patient department. On discharge he still had a slightly enlarged axillary gland and the sore was covered with a firmly adherent tough black scab measuring 1½ by 1 in. (3.8 by 2.5 cm.). The wound healed in the usual fashion.

Discussion

The opportunity given by a small outbreak of anthrax was used to test the clinical efficiency of chloramphenicol in cutaneous anthrax. Except for Case 1, in which the patient was *in extremis* on admission and died, all cases recovered. Only Case 1 had an enlarged spleen, and the disease appeared to be limited to the skin; but, owing to a lack of blood culture facilities, septicaemia cannot be entirely excluded. The small proportion of those affected compared with those at risk and the continued exposure of the mother of Case 4 raise a suspicion that these Indian labourers have a certain amount of resistance against acquiring this infection. Experience at other times has shown that the untreated disease is uniformly fatal. Case 1 shows that the strain was a virulent one.

Clinical appearances were typical of anthrax. All smears showed the typical morphological characters, and cultures on nutrient gelatin gave the typical spore-forming organism. Capsules were demonstrated by polychrome staining, and the suspensions of the cultures were positive to the malachite green test.

Summary

Cutaneous anthrax in four patients aged from 10 months to 55 years was treated with chloramphenicol with an initial dose of 60 mg. per kg. of body weight and a maintenance dose of 30 mg./kg. eight-hourly for 60 hours, then 15 mg./kg. eight-hourly for 48 hours, and finally 7.5 mg./kg. eight-hourly for a further 48 hours. All four cases showed rapid improvement leading to cure.

One case was treated on the usual lines with penicillin, sulphadiazine, and arsenic as a control. The series is too small to demonstrate the superiority of either method, each appearing equally effective.

It is a pleasure to acknowledge the help given by Messrs. Parke, Davis and Co., who supplied the chloramphenicol ("chloromycetin") and obtained permission from the Government of India to use it in these cases.

The medical section of the Library Association will hold its first week-end conference at University Hall, Liverpool, from Friday evening, March 28, to Monday midday, March 31. The programme will include an address by Sir Henry Cohen on the romance of words; a symposium on three types of medical libraries by Miss L. B. Jones, Mr. W. A. Lee, and Mr. G. Wilson; visits to the libraries of the Liverpool Medical Institution, Liverpool University, and the School of Tropical Medicine, and to the Speke Works of Evans' Medical Supplies. There will be a reception at the Liverpool Medical Institution, a visit to Speke Hall, and a coach excursion to Llangollen. Attendance at the conference is open to medical men as well as to librarians, and those who are interested are invited to write to the hon. secretary of the Medical Section of the Library Association, c/o the British Dental Association Library, 13, Hill Street, London, W.1.

BLEEDING MECKEL'S DIVERTICULUM

A REPORT OF TWO CASES

BY

JOHN N. WALTON, M.B., M.R.C.P.

Late Medical Registrar

AND

NORMA D. LILL, M.B., B.S.

*Late Senior House Officer**The Royal Victoria Infirmary, Newcastle-upon-Tyne*

A Meckel's diverticulum remains as a vestigial remnant of the vitelline duct in between 1 and 2% of individuals; Harkins (1933) found the anomaly in some form in 1.3% of over 25,000 necropsies.

Intestinal obstruction is said to be the most common complication (Taylor, 1947; Haber, 1947), but out of 1,605 cases from the literature Moses (1947) found that the presenting disorder was haemorrhage in 496 (30.9%), intestinal obstruction in 383 (23.8%), perforation in 222 (13.8%), a Littre's hernia in 188 (11.7%), and diverticulitis in 165 (10.3%). The incidence of the whole group of disorders is more than twice as great in males as in females.

In the cases here reported the bleeding was intractable and required urgent surgical intervention.

Case 1

A salesman aged 27 was admitted to the Royal Victoria Infirmary under Dr. A. G. Ogilvie on the morning of August 23, 1950. He had woken feeling nauseated, weak, and faint, and perspiring profusely. On going to the w.c. he passed a large amount of dark semi-fluid material per rectum.

Five years previously, while in the Army in India, he had had a similar experience and had received a blood transfusion. Investigation revealed no gastro-intestinal abnormality. For the past two years he had had vague lower abdominal discomfort after meals.

On examination he looked healthy, not evidently in pain. The pulse rate was 64 a minute, blood pressure 120/70. Abdominal palpation revealed nothing significant, but on rectal examination the examining finger was stained with dark-red blood. No other physical abnormality was noted.

The haemoglobin on admission was 75% (11.25 g./100 ml.), Hess's capillary fragility test was negative, and the bleeding and clotting times were normal.

Some four hours after admission the patient suddenly became pale, anxious, and sweating; the pulse rate rose to 96, and the blood pressure fell to 100/50. Ten minutes later he passed much dark-red blood per rectum. After a transfusion of 2 pints (1.14 litres) of compatible whole blood he improved. It was thought that the bleeding was from a duodenal ulcer, an intestinal polyp, or a Meckel's diverticulum.

The following day he again had a severe haemorrhage, necessitating further transfusion. Professor F. H. Bentley was consulted, and agreed that if there was evidence of further bleeding an emergency laparotomy should be performed. Radiographic examination, gastroscopy, and sigmoidoscopy were, for obvious reasons, not carried out.

On the morning of August 27 the patient again had a severe haemorrhage; his haemoglobin fell to 56% (8.4 g./100 ml.), and another continuous drip transfusion was begun.

Operation.—At 3 p.m. Professor Bentley opened the abdomen through a right para-umbilical paramedian incision;

the posterior-wall of the duodenum was felt to be a little thickened, but no ulcer appeared to be present. The caecum and lower ileum were filled with blood. Some 2 ft. (61 cm.) above the ileo-caecal valve a Meckel's diverticulum, about 4 in. (10 cm.) in length, was found protruding from the antimesenteric border of the gut. Blood filled the diverticulum and the ileum for some 12 in. (30.5 cm.) proximal to it; above this point the bowel was collapsed. Since it was evident that the diverticulum was the site of the haemorrhage it was excised.

The mucosa of the last inch (2.5 cm.) of the diverticulum showed multiple petechial haemorrhages and two superficial ulcers each about 3 mm. in diameter; in the base of one of these could be seen the mouth of a small vessel. The proximal portion was macroscopically normal. Dr. A. H. Cameron reported that histological examination showed acute ulceration, with no evidence of gastric heterotopia.

The patient made a good recovery, although gastric aspiration and intravenous therapy were necessary for 36 hours owing to moderate abdominal distension. The stools were free from occult blood within five days. On discharge on September 11 he felt well and his haemoglobin was 96% (14.4 g./100 ml.).

Case 2

A male telephonist aged 17 was admitted to the Royal Victoria Infirmary at 2.30 a.m. on July 15, 1951, under the care of Mr. John Brumwell. He had been perfectly well until two days before admission, when he began to pass small quantities of dark-red blood per rectum. This was unaccompanied by other symptoms until 24 hours later, when he began to feel weak and faint and to sweat profusely. At 1.45 o'clock on the morning of admission he woke with an urgent desire to move his bowels, fainted on getting out of bed, and passed a further large quantity of dark-red blood.

On admission he was anxious, sighing, and restless but not in pain. His conjunctivae and mucous membranes were blanched, pulse rate 120, and blood pressure 100/60. There was no tenderness or mass on abdominal palpation, but on rectal examination the examining finger was stained with dark-red blood.

A blood transfusion was begun immediately, and over the next 24 hours he received 9 pints (5.1 litres) of whole blood, with considerable improvement. At one stage his haemoglobin had fallen to 45% (6.5 g./100 ml.).

On July 20 he was transferred to a medical ward for investigation under the care of Dr. A. G. Ogilvie. His general condition was then good; pulse 85, blood pressure 130/70, and haemoglobin 66% (9.5 g./100 ml.).

Two days later he suddenly became weak and faint, vomited clear watery material, and passed a large dark-red fluid stool; despite continuous transfusion the bleeding continued. The clinical picture was so reminiscent of Case 1 that a firm clinical diagnosis of bleeding from a Meckel's diverticulum was made. Mr. Denis Hindmarsh was consulted, and agreed to carry out laparotomy.

Operation.—The abdomen was opened through a right paramedian incision. The large intestine and lower ileum were found to be filled with blood. A Meckel's diverticulum was identified, about 2 in. (5 cm.) in length, and the distal end was clearly thickened; it was removed together with a "wedge" of intestinal wall.

Dr. J. Hart Mercer reported on the specimen as follows: "The diverticulum shows a fairly deep oval ulcer in the floor of which no obvious vessel is visible to the naked eye. The mucosa macroscopically is mostly of the small intestinal type, but at the edge of the specimen some distance from the ulcer a thicker mucosa of more luxuriant appearance is seen. Histological examination reveals an active chronic peptic ulcer: the mucosa immediately surrounding it is of intestinal type, but further away gastric mucosa is seen."

The patient made a good and uneventful recovery from the operation, and on discharge on August 3 his haemoglobin was 89% (12.9 g./100 ml.).

Discussion

In the reported cases of haemorrhage from a Meckel's diverticulum a correct pre-operative diagnosis has rarely been made, except in children. In Case 1, although ulceration in a diverticulum was considered as a possibility, no firm diagnosis was reached before operation; in the second case, however, the similarity of the clinical picture to that in the first patient was striking and enabled the diagnosis to be made confidently. The character of the blood passed per rectum weighed heavily in pointing out the offending organ; it was dark red in colour, intermediate between the characteristic tarry stool of melaena from a duodenal ulcer and the bright-red blood of haemorrhage from a lesion of the colon. This point has been stressed by Murray (1947). A second feature of value in the differential diagnosis was that both patients vomited clear, watery fluid containing no blood.

Schaetz (1925) described the presence of areas of heterotopic gastric mucosa in 5 out of 30 diverticula examined, and it has been assumed that, as occurred in our Case 2, haemorrhage is invariably the result of ulceration in or around such islands (Haber, 1947; Taylor, 1947). However, Chesterman (1935) pointed out that ulceration can occur in the absence of gastric mucosa, explained by Winkelbauer (1929) as being due to irregular peristalsis producing invagination of the apex of the diverticulum; this is possibly the explanation in Case 1, as the lesions were confined to the tip.

Haemorrhage from a Meckel's diverticulum may produce a serious threat to life. It should be suspected in patients suffering from melaena of the type described; if haemorrhage is recurrent laparotomy is indicated, since the risks of an adequately performed operation are slight. If surgical treatment is not required in the acute stage a Meckel's diverticulum may occasionally be demonstrated radiologically (Rousseau and Martin, 1943).

Summary

Two cases of bleeding due to ulceration in a Meckel's diverticulum are reported. Cure followed excision of the diverticulum in each case.

One specimen showed acute ulceration and no gastric heterotopia; the other contained gastric mucosa, and a chronic peptic ulcer was present.

It is suggested that the character and colour of the blood passed per rectum—that is, dark red, as distinct from the tarry stool of a duodenal ulcer and the bright-red blood of a colonic lesion—may enable this syndrome to be diagnosed pre-operatively.

We are indebted to Dr. A. G. Ogilvie for permission to publish these cases, to Professor F. H. Bentley and Mr. Denis Hindmarsh for details of the surgical treatment, and to Dr. A. H. Cameron and Dr. J. Hart Mercer for the pathological reports.

Medical Memoranda

Accelerated Ossification in a Cretin caused by High Thyroid Dosage

The following case is reported because it is not generally known, and is not cited in paediatric textbooks, that high thyroid dosage in cretinism may cause advanced ossification, and because it demonstrates the advisability, during treatment, of taking serial radiographs of the ossific centres if maximal dosage within the limits of clinical tolerance is to be given.

Case Report

The patient was a full-term female infant with a birth weight of 6 lb. 13 oz. (3.1 kg.). She came under observation at 14 weeks of age, when the mother reported that the baby had seemed normal until 10 to 12 weeks, when she became drowsy, stopped smiling, lost interest, developed a feeble hoarse cry, and altered in facial appearance. These symptoms had since progressed, and on examination the baby, which then weighed 8 lb. 7 oz. (3.8 kg.), was seen to be a typical cretin (Figs. 1 and 2), with lethargy, coarse expressionless features, thick protruding tongue, dry yellow skin, puffy hands, large abdomen, and umbilical hernia. She did not watch other persons, the eyes did not follow a moving object, and there was no smile. In the prone position the head slumped down, and in no position of the body was it held steady. Radiographs showed gross delay in ossification in that no centres were visible for the cuboids, the heads of the tibiae, or the wrists.

It was decided to increase thyroid dosage as quickly as practicable to the limits of clinical tolerance on the grounds (a) that often the mental development of cretins does not progress favourably on the customary schedules even when treatment begins early (Warkany, 1950); (b) that some poor results may be due to underdosage attributable to faulty assay, deterioration, or impaired absorption; and (c) that other poor results may be due to initial slowness in building the dose to a maintenance level.

The initial treatment took place in hospital, dry thyroid (B.P.) being given in doses of 1/10, 1/8, 1/4, and 1/2 gr.

FIG. 1.—Face of the child at 14 weeks.

FIG. 2.—The child at 14 weeks.

(6.5, 8, 16, and 32 mg.) on the first, second, third, and fourth days, respectively, and then $\frac{1}{2}$ gr. (32 mg.) on each of the remaining 14 days of the in-patient period: the subsequent increments (see Table) were prescribed from the out-patient clinic. Within 19 days of the beginning of

Dosage of Dry Thyroid and Weight of Infant

Age in Months	Average Daily Dose of Dry Thyroid (B.P.)	Weight
5-6	1.2 gr. (78 mg.)	At 6 months 12.1 lb. (5.49 kg.)
7-8	1.7 " (110.5 mg.)	" 8 " 14.6 " (6.62 kg.)
9-10	2.2 " (143 mg.)	" 10 " 18.8 " (8.53 kg.)
11-12	2.8 " (182 mg.)	" 12 " 22.2 " (10.07 kg.)

treatment the typical therapeutic response was obvious and the baby improved dramatically in appearance and general symptoms. She continued under close observation, being examined and weighed at weekly intervals, and the parents, who were regarded as reliable observers, were informed of the issues and asked to report any looseness of the motions, undue sweating, restlessness, or other untoward symptom which could be regarded as evidence of intolerance to the increasing thyroid dosage. They also recorded the sleeping pulse rate.

No clinical evidence of intolerance did, however, occur, even though an average daily dose of 2.8 gr. (182 mg.) was reached during the eleventh and twelfth months; it was at this stage decided to make no further increase. At 15 months radiographs of the wrist (Fig. 3) showed that ossification, which had initially been retarded, was now very advanced. Six carpal centres were present as well as those for the lower end of the radius and the head of the fifth metacarpal. According to the standards described by Todd (1937), ossification had therefore advanced to a degree expected in a female child of 4 years 3 months. The patient's length, which was 22½ in. (57.2 cm.) at 18 weeks of age, was now 31 in. (78.7 cm.) and her weight was 23½ lb. (10.7 kg.).

FIG. 3.—Radiograph of wrist at 15 months.

From 15 months of age the thyroid dose was substantially reduced, but her bone age at 3 years was still advanced, being equivalent to that of a child of 5 years 9 months (Todd, 1937). Her height was 39½ in. (99 cm.). A satisfactory aspect of the case was that the child's mental development seemed to be within normal limits and she was also tall, but a future possibility which must be considered is that of premature union of the epiphyses with the diaphyses of the growing bones.

ADDENDUM.—Since the submission of this report for publication attention has also been drawn by Drs. B. Schlesinger and O. D. Fisher (*Lancet*, 1951, 2, 289) to the acceleration of ossification that may follow high thyroid dosage in cretinism.

Bacterial Endocarditis Caused by Coagulase-Negative Staph. Albus

Matthew (1951) reports two fatal cases of bacterial endocarditis in which the infecting organism was a coagulase-negative *Staphylococcus albus* and comments on the rarity of this organism as a cause. A similar case is here presented with brief clinical details; recovery took place after treatment with penicillin and streptomycin.

Case Report

A man aged 72 was admitted to hospital on August 18, 1950. He gave no past history of acute rheumatism, but had had an attack of mild congestive failure after unwonted exertion two years before; at this time an apical systolic murmur was heard and an x-ray film showed cardiac enlargement; recovery was rapid and no further symptoms occurred.

The present illness started four weeks before admission, with fever up to 101° F. (38.3° C.), general malaise, headache, night sweats, and shooting pains in the hands and legs; the serum twice showed no agglutination with enteric, salmonella, or brucella organisms. The patient gave no history of furunculosis, but his wife had a whitlow during the month preceding his illness.

On examination general appearances were normal except for some pallor of mucous membranes. His temperature was 99.4° F. (37.4° C.), pulse rate 100, and respirations 22. Clinical enlargement of the heart was noted, a systolic murmur was heard over most of the praecordium, and a soft diastolic murmur, which became much louder in the course of a week, down the left side of the sternum. The spleen was just palpable. No finger-clubbing or peripheral embolic phenomena were found, though a week after admission a small subconjunctival petechial haemorrhage was noted. His blood pressure was 150/80; E.S.R. (corrected), 18 mm. in one hour; R.B.C., 4,400,000; Hb, 74%; W.B.C., 9,400 (neutrophils 85%); and urine deposit showed occasional red cells. Blood culture gave a haemolytic coagulase-negative *Staph. albus*; this was repeated with a similar result. The organism was insensitive to "sulphatriad," moderately sensitive to "aureomycin," chloramphenicol, and streptomycin, and sensitive to 6 units of penicillin in 1 ml. but insensitive to 3 units in 1 ml.

On August 23 penicillin, 1,000,000 units, soon increased to 2,000,000 and then to 4,000,000 units daily, was started. Three days later the patient complained of pain of indefinite type in his chest, but this quickly subsided and no evidence of pericarditis was found at any time. On September 3, as the temperature was still rising on most evenings to 100° F. (37.8° C.) or higher, streptomycin, 2 g. daily, was given in addition. Blood culture a week later was sterile, the spleen was no longer palpable, and the temperature gradually became and remained normal. A further blood culture was sterile, no R.B.C. were found in the urine, and Hb was 90%. Penicillin was discontinued on September 22 and streptomycin on October 13, and the patient returned home for further rest and convalescence.

It was soon necessary to readmit him for 14 days on account of acute dermatitis, which was thought to be possibly due to streptomycin and which responded to anti-histamine drugs and local treatment. On returning home a second time he unluckily developed a small pulmonary embolus, but soon recovered. At the time of writing he is free of symptoms and leading a relatively active life.

I wish to thank Dr. Goodman Platts and Dr. Olive Cameron for pathological work and Dr. E. S. Vergette for clinical notes.

Reviews

TO LOVE AND TO CHERISH

Patterns of Marriage. A Study of Marriage Relationships in the Urban Working Classes. By Eliot Slater, M.A., M.D., F.R.C.P., and Moya Woodside. (Pp. 311. 17s. 6d.) London: Cassell and Co. 1951.

This book tells how in 1943 Dr. Slater and Mrs. Woodside began collecting information about marriage. They took a sample of 100 neurotic soldiers and 100 physically ill soldiers (whether because of infection or injury at the front or from quiet areas) and interviewed them and their wives, seeking a full history and inquiring particularly into their marriage relationships. No unwilling informants were included. Most of the persons were from the manual-worker class, only 12 had matriculated, and fewer than 50 had been educated after the age of 14.

This must be one of the first works about marriage in this level of society. Its revelation of the drabness of pre-war working-class life and monotony at home, or toleration of disorder and despair, makes it a social document of importance. Astonishing numbers of people drift into acquaintanceship and after two years marry. But they seem to get married *for something*—a home—rather than *to someone*—their partner. One-fifth had married before the age of 21, three-quarters before 26. But, with marriage, culture ceased; women became tied to their homes in a way many are likely to refuse in future; religion interested few; politics reflected more often an emotional attitude to life than a considered outlook.

It is impossible to summarize the mass of statistically verified information we are given. For psychiatrists the book must be a tonic. Many opinions gained in the out-patient department or consulting-room are exploded. In theory, extramarital attachments were condemned by the subjects; practice proved somewhat different though not as different as might have been guessed. Less than 1 in 10 of the women had contracted forced marriages, a view suggesting some difference from that of the Registrar-General's report for 1937-8. Not 1 out of 100 neurotic men admitted impotence, but 1 out of 200 husbands admitted being henpecked. Past operations, especially gynaecological ones, impair orgasm in women. Mrs. Grundy is still rampant. Neither family doctors, health visitors, nor gynaecologists take adequate initiative to explain contraceptive techniques. Some of the happiest marriages were childless; no correlation was found between happiness and fertility. The authors are not pessimistic about the future. Despite overcrowding, conditions are improving, and higher standards of teaching may be expected to alter matters gradually. Further, despite tragic marriages, there are many surprising cases showing how difficulties have been surmounted or the expected separation did not occur.

It would be well to remember that the authors do not claim that their sampling was perfect. Factors such as prolonged absence from home, wartime work for women, and the roseate hues in which the dreary past were recalled make some of the information less reliable than the authors, or we, should like. But all social agencies will be grateful for this stimulating information, which we suspect Dr. Slater and Mrs. Woodside them-

selves hope will be questioned, criticized, and reflected upon to the encouragement of progressive social planning.

HENRY WILSON.

ARTIFICIAL IMMUNIZATION

Bacterial and Virus Diseases. Antisera, Toxoids, Vaccines, and Tuberculins in Prophylaxis and Treatment. By H. J. Parish, M.D., F.R.C.P.Ed., D.P.H. 2nd ed. (Pp. 204; illustrated. 10s. 6d.) Edinburgh: E. and S. Livingstone. 1951.

It is a mistake to suppose that chemotherapy has materially affected the usefulness of artificial immunization. The sulphonamides and antibiotics are mercifully most effective in just those conditions—pyogenic coccal infections, cerebrospinal fever, gonorrhoea, and anthrax—in which for one reason or another serum or other such treatment was least certain in its effects. The pre-eminence of immunization, both active and passive, in the treatment of diphtheria and tetanus remains unimpaired. The prophylactic value of vaccines is not diminished: indeed, the past few years have seen considerable advances in their application to whooping-cough, tuberculosis, and virus diseases. For those intending to make the best possible use of all such procedures in prevention and treatment and in the diagnosis of the immune state of the individual this book is an admirable guide. Although presenting theory adequately and clearly, it is essentially practical, since the author gives full instructions for carrying out every kind of injection or inoculation, defines the indications for them, and discusses such risks as may be involved and the precautions to be taken against them. He shows a nice discrimination in ignoring certain vaccines for whose use there is no favourable evidence, and in crediting to chemotherapy the major share in treating some of the infections for which antibacterial sera are also available.

L. P. GARROD.

THE CHORDATES

The Chordates. By Herbert W. Rand, Ph.D. (Pp. 862; 609 illustrations. £2 5s.) London: H. K. Lewis. 1950.

Not least of the features which raise Professor Rand's work above the general run of textbooks of vertebrate comparative anatomy is the fact that he can write really well. He recalls in his preface the days when students were few and had ample time to read, and, less nostalgically, the later expansion of university biology in America. "An earlier sense of freedom and leisure to work thoughtfully was insidiously superseded by a sense of crowding, pressure, and haste. . . . It was evident that the student of the later years was not reading much and could not be expected to." So he wrote the present book, to combine with an adequate factual content some discussion of the wider human significance of the subject.

In the first part he discusses the basic structure of vertebrates, in the second part the history and principles of comparative anatomy, and in the third the chordates, group by group. All of his well-chosen material is concisely, lucidly, and interestingly presented, and the text is accompanied by a wealth of good illustrations, including a photograph, which his students will treasure, of the author embroiled with a couple of chimpanzees.

Finally, in an epilogue entitled "What Comes of Studying Vertebrates," Professor Rand lets himself go. "The present classification of man as a primate mammalian chordate is based entirely on his bodily structure.

The ideal of modern classification is that it should express genetic relationship and that it should be so devised as to indicate the points where major and crucial evolutionary steps have been taken—i.e., the initiation of important new lines of specialization. The primates took such a step. Their shaping of the environment to their own uses is perhaps the most radical step in the whole course of evolution. . . . The time will come, and perhaps now is, when men should be assigned to an additional Class of vertebrates." And so he anticipates the erection of a new Class VII, Anthropeida. The lemurs and tarsiers would remain among the mammals as an Order closely allied to the insectivores. The remaining primates would constitute the new Class, which would necessarily be subdivided into two subclasses. The first, including the monkeys and great apes, "could be called PROTOANTHROPEIDA—a group analogous to SUBCLASS PROTOTHERIA of Mammalia." The second is to contain the present family Hominidae. "In some far-distant future, when man's social wisdom shall have so far caught up with his inventive intelligence as to justify the name for him, this SUBCLASS might be designated as SAPIENTIA."

G. P. WELLS.

BLOOD COAGULATION

Die Blutgerinnung in Theorie und Praxis. By Dr. Josef Schmid. Wiener Beiträge zur Inneren Medizin, Volume 4. (Pp. 444; 135 figures. M. 50.) Vienna: Verlag Wilhelm Maudrich. 1951.

The coagulation of the blood has become a matter of bewildering complexity. The simple equations formerly held to explain the process are now outmoded and new factors are constantly being discovered or, more precisely, their existence is constantly being inferred. If further evidence of this state of affairs were needed, it can be found in this book, in which the situation as it stood at the close of 1950 is adequately reviewed.

The author has forsaken the conventional arrangement of similar monographs, in which the physiology and biochemistry of the clotting process is first reviewed and is followed by a description of the clinical states which arise from its disturbance. After a brief historical review he devotes sections to the thrombokinas, prothrombokinas, and antithrombokinas, turning aside then to consider haemophilia, haemorrhagic states due to circulating anticoagulants, and thrombocytopenia. Then follow chapters on prothrombin, antiprothrombin, and vitamin K, succeeded by sections on hypothrombinaemia and the thromboses. He concludes with discussions of the prothrombin activators, fibrinogen, thrombin, thrombin inhibitor, clot retraction, and fibrinolysis.

The individual sections are full and up-to-date, but the arrangement is not entirely logical and robs the book of cohesion. There are detailed descriptions of technical methods which will be useful to the laboratory worker, but the clinician will need to seek enlightenment elsewhere. The book has the hallmarks of a painstaking compilation of other workers' observations and opinions, unlevaned by critical selection. The reader who is not a professional "coagulationist" will regret the author's omission of a chapter in which the actual mechanism of clotting is described and the interrelationship of the many factors set out. His presentation conceals the unity of the process and tends to perpetuate the view that it consists of a number of asynchronous and almost unconnected reactions.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 12 1952

VASCULAR SPASM

Knowledge of the peripheral circulation has been acquired slowly, and, despite a great volume of original work, facts of fundamental importance still elude discovery. From the time of William Harvey up to roughly the end of the nineteenth century the main interest of the circulatory physiologist was in the heart and great vessels. Only in the last thirty years or so has the work of Ebbecke, Krogh, Lewis, Gollwitzer-Meier, and a host of others directed attention to the more minute vessels. A variety of techniques have been used in the investigation of the circulation, and some of the more recently developed methods—notably the use of radiography of the larger vessels by Trueta and his associates¹ and, in the case of the minute vessels, the delicate micro-manipulative techniques of Zweifach²—have given us a much more dynamic and detailed picture of the peripheral vascular tree. At the same time work with the radioactive isotopes has greatly expanded the scope of research, so that the complicated and continuously changing pattern of the circulation is now better understood.

At the risk of being dogmatic it may be said that, from the functional point of view, the peripheral circulation can be considered in three parts: first, the proximal vessels, changes in the calibre of which are chiefly passive in nature; secondly, the smaller arteries, veins, arterioles, and venules, which respond to both nervous and chemical stimuli; and, thirdly, the more minute vessels (capillaries, pre-capillaries, and metarterioles), which are subject to periodic changes in calibre, a phasic activity which has been termed "vasomotion." These last vessels, besides responding to the better-known nervous and chemical stimuli, are also influenced by enzymes such as renin, and the more recently described vasotropic factors V.E.M. (vaso-excitor material) and V.D.M. (vaso-depressor material). The clinician may find himself in danger of being overwhelmed by the many and varied additions to knowledge and sometimes be tempted to give too glib an explanation of certain

manifestations of organic vascular disease. How often, for example, does he invoke "spasm" as an explanation of the otherwise inexplicable? Spasm has, in fact, become a medical cliché. Pickering³ has recently referred to some common misconceptions about spasm in arterial disease and has emphasized how closely organic arterial occlusion can mimic vascular spasm. Similar misconceptions probably exist about the venous circulation, for Ochsner and de Bakey⁴ have referred to the importance of spasm in venous thrombosis; yet it is very doubtful whether spasm plays any part in the majority of cases.

With so much interest in the minutiae of the circulation it is easy to assume that knowledge of the large vessels is fairly complete. That this is not so is shown in the opening pages of this issue by Mr. J. B. Kinmonth, who reports the results of some fundamental research into the behaviour of large arteries. It will be recalled that Trueta and his co-workers,¹ when investigating the crush syndrome, applied a tourniquet to the thighs of rabbits and observed, by a radiographic technique, contraction of the arteries in the contralateral limb—a finding which they attributed to reflex arterial spasm. The object of Mr. Kinmonth's investigation was to determine the cause and cure of spasm in the large arteries. By directly observing the femoral arteries in experimental animals whose blood pressure was recorded continuously, he has shown that the large arteries behave in a much more passive fashion than is commonly supposed. The changes in arterial calibre seen in Trueta's experiments are now known to be directly related to falling systemic blood pressure and not to reflex arterial spasm. It has further been demonstrated that neither faradic stimulation of the large arteries and lumbar sympathetic chain nor the intravenous injection of adrenaline has any direct effect on the diameter of the large arteries, although these stimuli can cause profound changes in the more peripheral vessels.

Many of these experimental findings in the rabbit have been confirmed in man, and Kinmonth has found that spasm of the proximal arteries can be induced only by direct trauma, the irritability of the vessels varying at different times and in different subjects. The upper part of the femoral artery has no vasoconstrictor nerves, and the exact level at which this nerve supply begins has not been determined. Wilde,⁵ however, has shown by microdissection that the nerves to the upper femoral artery are purely sensory in character, and that vasoconstrictor fibres are distributed only to the more distal vessels and muscular tributaries. From the practical point of

⁵ *Brit. J. Surg.*, 1951, 39, 97.

view this means that sympathetic nerve fibres are responsible for neither the initiation nor the maintenance of spasm in large arteries. This must necessarily influence treatment of the spasm which is sometimes seen in association with supracondylar fracture of the humerus and other types of direct arterial injury. Paravertebral block, peri-arterial stripping, and arteriectomy clearly have no place in treatment and are absolutely contraindicated. Early exploration and decompression of the affected artery is imperative, and Kinmonth has found that the local application of 2.5% papaverine sulphate solution is most effective in relaxing spasm. Locally applied procaine, caffeine, and warm saline packs are much less effective and less reliable, while the intravenous injection of papaverine sulphate is as ineffective in the human being as it is in the rabbit.

SHORTAGE OF X-RAY FILMS

The Ministry of Health stated recently: "There is a serious world shortage of x-ray films due to increasing usage in all countries. In this country usage during the first six months of 1951 was 16% greater than in the corresponding period of 1950 and was at a rate about 60% greater than in 1947."¹ Since the spring of 1951 this shortage of films, and the position of all those who use them, has been deplorable. An agreement between the manufacturers has just been reached by which an allocation is to be made to hospitals according to previous consumption. A radiologist in private practice will receive a percentage of his "usage" which will leave him with time to devote to his hobbies. Clearly an x-ray department would have difficulty in maintaining an efficient service on approximately 40% of its film supply, and the cuts at some hospitals may approach this.

The manufacturers say that the various theories which have been advanced to account for the failure to supply films are untrue. It is denied that there has been any faulty distribution, shortage of raw materials, or stock piling, and that closing the factories for a fortnight in the summer or an increased export accounts for the position. The official figures for exported film which has passed through the customs during the eleven months January–November in each year are 7,591,000 sq. ft. (1949); 8,632,000 sq. ft. (1950), and 13,997,000 sq. ft. (1951). An average large teaching hospital uses about 130,000 sq. ft. of film in a year. The film exported in June, 1951, alone was 3,746,000 sq. ft. and would have met the needs of 28 teaching hospitals for a year. The manufacturers and the Ministry imply that the root

cause is "increasing usage," and the ministerial letter continues with advice on economy. This advice strikes a nice balance between needs and risks.

A praiseworthy act of the Ministry in the early days of the National Health Service was to develop the x-ray services and to install much new plant. In the last two years there have been established or added 560 major units in various clinics. These centres do not work with mass miniature apparatus but use the standard large film.

The committee of every hospital in the country has probably discussed the expense of its x-ray department and methods of reducing it. In the summer of 1951 an earnest attempt was made by most hospitals to economize. The long examinations for the kidney, gall-bladder, and intestinal tract were curtailed, with a decrease in efficiency and with little saving in annual expenditure because the number of patients was rising. Within recent years many radiographic techniques have changed and new methods have been evolved, particularly for the skull, chest, and vascular system. None saves films, except mass miniature radiography. Tomography is a most expensive addition. In the absence of expert supervision a physician may be presented with six or more large tomograms which may fail to delineate the lesion either because the "cut" is at the wrong level or the radiographer has made an error in exposure. In addition the usefulness of the tomogram is not understood by many clinicians, and the examination is often requested for lesions which an experienced radiologist would know to be unsuitable.

The consumption of x-ray films in hospitals and clinics is difficult to limit, particularly in large departments which strive for a high standard. Waste occurs each winter by a variation in power at peak hours which disorganizes the exposure charts of every radiographer. Films are wasted by the duplication of examinations in out-patients and wards, by requesting films of both knees when one is affected, by ordering postero-anterior and lateral films of the chest before the former film has been inspected. These are obvious but common mistakes. Equally appreciated is the zealous houseman who tries to anticipate every wish of his consultant. The arrival of a new batch of medical officers is reflected in an increase in the work of auxiliary departments, but this increase is temporary.

The staggering demand made on manufacturers of film has increased progressively in the last few years in spite of instructions to the junior medical staff and restrictions on their privilege. Fortunately the graph of consumption shows some sign of check in its rapid ascent. It is safe to say that further economy in x-ray departments will be very difficult to obtain,

¹ *British Medical Journal Supplement*, 1951, 2, 255.

because so much effort has already been made and because demands on these departments will not be less. A great saving in film, measured by the thousand square feet, could be made by wider use of miniature film, particularly in chest clinics. The experts at the Ministry are aware of this fact and have been engaged during the last six months testing various types of apparatus and films.

Apart from radiology, photographic film serves many functions—in industry, entertainment, and pleasant recreation. It would not be difficult in a welfare state to place these items in an order of importance and priority. This has not been done. Hope for the future rests on an increased production, which is promised in the summer, but this expectation is denied by a shortage of silver, which is also promised.

The components of x-ray film are imported from hard currency countries, and one explanation for the position is that it is necessary to maintain and even increase the export of films as part of the general effort to survive beyond the present period of financial difficulty. If this is the position a statement of the facts as they refer to x-ray films would be timely and well received. It would procure greater and more enduring economy in hospitals than any other method. As one radiologist has said, "Should we have food for the fit or films for the failing?" It is a difficult question to answer.

TESTS OF RESPIRATORY FUNCTION

Those who study the more chronic diseases of the lungs have for long felt the need for a measure of respiratory function. Skiagrams give little indication of the degrees of disability. Thus in welder's siderosis the radiological changes are gross and the disability is slight, while the reverse holds for asbestosis. Similarly byssinosis causes extreme shortness of breath and early death without giving rise to any shadows on the x-ray film which could be regarded as specific. If some satisfactory method of studying the efficiency of respiration could be devised it might prove useful in indicating that damage was being done to the lungs of workers exposed to dangerous dusts before radiological evidence was forthcoming. Unfortunately, no test has so far proved ideal, partly because they are nearly all under voluntary control and thus dependent on the co-operation of the patient. The degree of this co-operation can never be estimated accurately, as has been shown by D'Silva and Mendel,¹ who compared results obtained in a student group giving full co-operation with those obtained in a similar control group of hospital patients not suffering from lung diseases. The difficulty applies particularly to the simple tests, such as chest measurement, exercise tolerance, and vital capacity, which up to the present have been most used. As a result many new methods have been developed.

The maximum breathing capacity, a test introduced by Hermannsen² in 1933 and developed in recent years by Couma,³ Wright,⁴ and Gilson and Hugh-Jones,⁵ is estimated by getting the patient to breathe as deeply and fast as he can while the volume of air moved per minute is measured. This test has not proved very satisfactory, since it is still under voluntary control, and D'Silva and Mendel have shown that an apparatus error, inherent in all spirometers, and which cannot easily be allowed for, becomes important at high respiratory rates. Donald⁶ found that patients with emphysema showed an impaired reaction to the inhalation of 4% carbon dioxide, and he therefore investigated the effect of this on 56 coal-miners with pneumoconiosis, in the hope that this test would throw some light on their disability. The results, however, were disappointing, for five subjects who had severe dyspnoea on the slightest exertion, as well as massive shadows on their x-ray films, reacted normally to carbon dioxide. In fact impaired reactions were found only in those who had considerable emphysema.

Motley, Lang, and Gordon⁷ carried out measurements on 100 miners with pulmonary symptoms and a long history of exposure to coal dust. They found that the residual air expressed as a percentage of the total lung volume was not significantly increased in a third of the cases. They suggest that the disability arises from fibrosis and the unequal alveolar aeration and perfusion, with consequent decrease in the amount of oxygen in the arterial blood. It is of course evident that the function of the lung is to oxygenate the blood, and that the amount of oxygen in the arterial blood can be a valuable guide to the efficiency of lung function. The range of reading between saturation and unsaturation is, however, very narrow, but this can be widened if the oxygen tension is altered. Motley and his colleagues found that a decrease in the saturation of oxygen in arterial blood after exercise was a significant finding in the assessment of disability. The resting arterial oxygen saturation alone was poorly correlated with impairment of pulmonary function, since the measurements of the exchange of respiratory gases might be normal at rest although grossly abnormal during exercise. In another review of the subject Motley⁸ suggested that the physiological tests of pulmonary function might be divided into five groups: those that measure lung and ventilation volume, such as vital capacity, maximum breathing capacity, and minute ventilation rate, at rest and during exercise; the residual air expressed quantitatively as a percentage of total lung volume; arterial blood oxygen saturation, at rest and during exercise; the oxygen uptake from inspired air; and increased pulmonary arterial pressure and pulmonary vascular resistance during exercise.

Elsewhere in this issue (p. 65) Dr. P. Hugh-Jones reports a further attempt to devise a simple scientific measure

⁷ *Amer. Rev. Tuberc.*, 1950, 61, 201.

⁸ *Penn. med. J.*, 1950, 53, 119.

of exercise tolerance. He has taken the commonly used stepping test, but instead of bothering with pulse rates and respiratory rates or subjective estimates of breathlessness he measures with the aid of an old gas-meter the air volume breathed per minute by the patient during exercise. The exercise is standardized so that it is the same for each patient regardless of his weight, and this is achieved by adjusting the height of the step and the rate of stepping, while the amount of work done in the five-minute test period is not enough to prove distressing.

This test is simple to carry out, requires only such apparatus as an ordinary consulting-room might have, and bears some relation to the activity of daily life. Hyperventilation through nervousness does not produce error owing to the way in which resting ventilation and exercise ventilation are combined in the final results. While the test may be used by itself in following, for instance, the treatment of heart failure, it still has to be combined with other investigations in studying industrial lung disease to separate out the fraction of exertion dyspnoea which is purely pulmonary in origin.

ACUTE INFECTIOUS LYMPHOCYTOSIS

An infectious disease in which recognizable illness is slight or absent and in which almost the only sign may be an excess of lymphocytes in the peripheral blood is not easily diagnosed. It is not surprising, therefore, that since Smith¹ first drew attention to acute infectious lymphocytosis as a clinical entity in 1941 little new knowledge has been added to the subject. Many of the reports have described small institutional outbreaks, and it has been the almost accidental finding of a high lymphocytosis on routine blood examination that has unmasked the "epidemic." The group of six cases reported in this week's issue by Dr. H. G. Dunn belongs to such a category, for all were associated with a nursery in the East End of London, and in four of them there was little reason to suspect a systemic illness. The contrast between infectious lymphocytosis and classical infectious mononucleosis is thus fairly clear-cut. In the latter condition some form of clinical illness is usual—although the signs may be diverse—the lymphocytes are atypical and immature, and heterophile antibody can be found in the blood serum. In acute infectious lymphocytosis, on the other hand, there may be few clinical signs or symptoms, although some cases have been described with gastro-intestinal upset or, as in Smith's early cases, with a mild infection of the upper respiratory tract. The leucocytosis, however, may be out of all proportion to the illness, and, as can be seen in two of Dunn's cases, counts of 70,000 or 80,000 are quite common. Further, unlike infectious mononucleosis, the cells are normal small mature lymphocytes. On these grounds, therefore, the two conditions can be distinguished with reasonable certainty, despite

the undoubted fact that all cases of infectious mononucleosis do not strictly conform to the canonical description.

Having said this, however, one must equally firmly assert that the presence of a lymphocytosis should not be regarded as necessarily implying the diagnosis of acute infectious lymphocytosis. Similar cell counts are seen in many other conditions. Pertussis is the most common, and it would be interesting to know whether the usual lymphocytic response is associated with the mild infection caused by *H. paraptussis* or, in the vaccinated child, by *H. pertussis*—illnesses which do not necessarily declare themselves with the characteristic whoop. Mumps, infectious hepatitis, certain stages in the recovery from acute infections, and sensitization itself—all these may induce a lymphocytosis, though, it is true, not usually of the magnitude seen in the infectious variety. It is worth pointing out that, although this condition was first seen only in young children, isolated examples in adults have now been recorded.^{2,3} A feature of the adult cases has been that the total white-cell counts have been much lower than those seen in children. The type of cell thus becomes of some importance in distinguishing the condition from infectious mononucleosis.

Five of Dunn's group of cases were associated with *Giardia lamblia* infestation, but it seems unlikely that this could explain such a high lymphocytosis. While Ormiston and his colleagues⁴ drew attention to a mild eosinophilia in some of their cases of giardiasis, they made no comment upon lymphocytosis, which could hardly have escaped notice if it had been present. Even so, the observation may be of importance in view of the complete uncertainty about the cause of the condition.

There is always the danger that ignorance may be masked by attaching a convenient diagnostic label to a condition about which there is much uncertainty. It is quite conceivable that acute infectious lymphocytosis should be regarded more as the reaction of the host to a variety of agents than as a specific entity: such a view takes into account the need to consider other manifestations of infection in any epidemiological study. Dunn's investigation raises the possibility that a closer observation of minor bowel upsets in children in institutions and day nurseries might be rewarding.

EXPERIMENT IN HAITI

Haiti, in the West Indies, the earliest state to be governed constitutionally by negroes, has been the field of a pilot project for reducing illiteracy and encouraging hygiene and social welfare.¹ The project, sponsored by Unesco and the Haitian Government, with the co-operation of the World Health Organization, was started two years ago in the rural area of Marbial, with a population of about 28,000. In this valley all the problems of overpopulation, land hunger, soil erosion, poverty, and declining agriculture were encountered. An anthropo-

logical survey was first undertaken, and a start was made with an educational programme to bring to the people elementary knowledge and simple skills. During the period of survey famine conditions followed an 11-months' drought, and some adults and children died of starvation; but even in normal years it is said that few of the peasants grow enough to feed their families from one harvest to the next, and they never have enough money to purchase adequate food in the interval. Except in relatively well-to-do families, meat is eaten perhaps only once a month, and fats of any sort are scarce. One of the tasks of the campaign was to teach the peasants to vary their diet, and not to despise such useful foods as grapefruit.

Illness in such a community is, of course, a catastrophe, and there is almost no medical assistance. A private doctor has gone twice a week to Marbial from the near-by town of Jacmel, but few could afford to pay his nominal fee or buy the medicines he prescribed. Malaria is endemic; many of the people suffer from yaws, and hookworm and tropical ulcers are common. There are herb doctors whose treatments are a mixture of common sense and magic and who are fairly skilful in childbirth, massage, and the setting of broken bones; their fees are modest and their intentions at least are good. Those undertaking the survey found a certain open-mindedness on health education. While the peasants often assign supernatural causes to illness and may resort to magic and charms in their search for cures, they do not hesitate to go to a qualified doctor when they can. They accept instruction on bodily and household cleanliness, perhaps out of a concern for prestige rather than for hygiene, but prestige may be a useful motive to play upon.

The early activities of the project have been in the fields of education, agriculture, and development of crafts and rural industries. The plan also provides for the setting up of a clinic and maternity centre, not only to meet the needs of the community for medical services, but to train teachers and workers in health education. The clinic is to be closely associated with the hospital at Jacmel. When a small clinic was opened in September, 1948, it proved almost too successful, for the doctor who came from Jacmel was quite unable to treat all the patients who flocked to him. In virgin areas such as this the approach to preventive medicine must be through curative medicine, which has much more appeal. No large-scale campaign of preventive medicine or sanitary engineering has been started, but energies so far have been directed towards obtaining the active co-operation of the people, so that they themselves can be enlisted in the effort to raise the social level of their community.

BEGINNING TO BREATHE

Recent correspondence in the *Journal*^{1, 2} has raised once more the question of the limits to our knowledge of the physiology of the newborn infant. From time to time we are all guilty of extrapolating back into neonatal life from the established physiological facts of adult life. We continue to do this in spite of a growing and

impressive body of knowledge which shows the infant to have marked functional differences from the adult. We should no more argue from the adult to the baby than we should from the cat to the whale; particular physiological reactions must be tested in the baby itself. Knowledge of the respiration of the newborn infant is a case in point. In spite of many observations and experiments, it is still true to say that the beginning of extrauterine respiration is not fully understood. Huggett³ in 1927 introduced to this country the technique of caesarean delivery of the foetus into a saline bath with the placental circulation intact. This gives an excellent experimental preparation, and he himself made observations of the foetal respiratory reflexes⁴ and was most impressed with the part which joint movements played in stimulating respiratory activity. This work was continued by Sir Joseph Barcroft,⁵ and he has left a widely quoted summary of his findings. Nevertheless, it is generally felt by obstetricians and physiologists that the last word has not been said on the subject.

Turning now to the newborn child, we are faced with respiratory behaviour that differs greatly from that of the adult. Gibberd⁶ has stressed the part played by extraneous nervous stimuli in regulating the minute volume of the newborn. However, when the infant sleeps quietly it must surely be dependent for respiratory control upon its visceral reflexes and gaseous equilibrium. Direct observation shows that periodic breathing is common in the healthy full-term infant, and almost universal in the otherwise normal premature infant. In adult life this type of breathing has a serious prognostic significance, or else may be associated with induced hypoxia, as has been so beautifully demonstrated by Haldane.⁷ It is no longer thought that the normal infant breathing air is suffering from hypoxia,⁸ so that the mechanisms which have been analysed by Haldane are not directly applicable to the baby.

It is only since the introduction of the body plethysmograph⁹ that the response of the infant to artificial gas mixtures has begun to be studied in a quantitative manner. Since its introduction the instrument has been modified¹⁰ and it is now possible to have infants sleeping normally in it for long periods. A recent accurate assessment by Cross and Warner¹¹ of infantile responses to high and low oxygen mixtures suggested the probability that the carotid-body reflex was more active in the newborn infant, and a later incomplete report¹² seems to show even greater activity of the peripheral chemoreceptors in the premature infant. In spite of this active reflex, it appears that no newborn baby has a good defence against prolonged hypoxia, as the medulla seems to become depressed in these circum-

stances. It should be stressed that this work is not yet confirmed. However, it underlines the importance of the baby as an object of separate physiological study.

One factor in the ability of the very young animal to withstand anoxia which deserves mention is its power of anaerobic metabolism. This was shown as long ago as 1870 by Paul Bert,¹³ and has been confirmed recently by Wilson and his colleagues.¹⁴ In spite of this the clinician should never rely upon it, and all efforts should be made to obtain normal oxygenation as soon as possible after delivery.

"PRISCOL" IN CEREBRAL ARTERIOSCLEROSIS

The symptoms of cerebral arteriosclerosis which, in the absence of acute episodes such as a cerebral thrombosis or haemorrhage, are probably due to chronic cerebral ischaemia are very resistant to any form of treatment. Vasodilators such as oral nicotinic acid have been used with only occasional success. In a recent issue of this *Journal* (October 13, 1951) Smith and Turton described the use of "priscol" in an arteriosclerotic patient who had severe executive dysphasia and difficulty in writing, together with emotional changes. Although the authors state that there was no evidence of a focal lesion the presence of executive dysphasia and dysgraphia with apparently normal comprehension of spoken speech and of writing suggests strongly that there was in fact focal damage in the left fronto-temporal region, but whether this resulted from a cerebral thrombosis or not is uncertain. The effect of an intravenous injection of 40 mg. priscol was dramatic: within a few minutes there was evidence of vasodilatation in the skin and retinal vessels and remarkable improvement in speech and writing ability. The improvement lasted about three hours, and the patient then relapsed into his original condition. The same effects followed a second injection, while there were no changes after intravenous injections of sterile water or of vitamin B₁. Oral administration of priscol was then tried in a dose of 25 mg. six times a day, and after 48 hours there was again remarkable improvement. Unfortunately the patient's condition gradually returned to its original state in spite of increasing doses.

Priscol (2-benzyl-4,5 imidazoline hydrochloride) has a complicated pharmacological action, but among other effects it has been shown experimentally to cause vasodilatation of the peripheral and coronary vessels,¹ and its effect on the cerebral vessels of the cat is illustrated in a letter on p. 106. In man a similar peripheral vasodilatation has been demonstrated after intravenous injection and to a lesser extent after oral administration.² The drug has been used with successful relief of symptoms in peripheral arterial disease, the best results being obtained when there is a large element of spasm as in Raynaud's disease, but improvement in intermittent claudication and in the

rest pains of occlusive arterial disease occurs in some patients.^{3,4} The question of spasm of cerebral vessels in association with cerebral arteriosclerosis is a debatable one, but in some patients the symptoms suggest that there may be episodes of arterial spasm. Although the action of priscol on the cerebral blood vessels is not known for certain the results in Smith and Turton's patient suggest that vasodilatation occurs, and an extended trial of the drug in suitable patients with cerebral arteriosclerosis would seem to be worth while.

"M. & B.I."

Medical and Biological Illustration enters its second year with the next number. In spite of the somewhat trying conditions prevailing in 1951, which made it an inauspicious year in which to launch a new publication, and in which cost of paper has risen steeply, the journal seems to have met a definite need, and already it has gained an encouraging readership abroad—principally in the United States.

Casual conversation, however, shows that there are still many working in the fields which the journal covers who have never heard of it. News spreads slowly, and there are so many journals on the library table that to overlook a new one may be forgiven. Seeing the cover only, some may decide that the journal is of a technical nature and therefore of no interest to them. It is true that there are technical articles, but many are general in scope, and are aimed at the user of illustration rather than the producer. The teacher is well served, and a new series covering all aspects of the preparation and publication of a medical book should have a wide appeal. Liberal illustrations make even the technical articles less indigestible for the non-technical user, and simple curiosity may make him aware of new developments without the need to assimilate the actual methods of production: he will often find these applicable to his work, whether clinical, research, or teaching. There are historical papers, too, which have no worrying technicalities. That the subject is growing is shown by the enlargement of the valuable abstract section, and the Association's foresight in sponsoring *Medical and Biological Illustration* is borne out by the news of a new journal, *Via Optica*, which is to appear in the United States. The *Journal of the Biological Photographic Association* is another American publication, but this affords little recognition to the medical artist, while our own journal caters for all branches.

This catholicity of interest is of especial importance in connexion with another event which is to take place at B.M.A. House in June, 1952, when the Medical Group of the Royal Photographic Society and the Medical Artists' Association are presenting a joint exhibition of illustration. This is the first time that the work of the two main branches of medical illustration will be seen together, and it augurs well for the future. Together with *M. & B.I.*, it implies the disappearance of the suspicion with which the painters and the photographers have been prone to regard each other—a suspicion which can only do harm to the wider aims of medical illustration.

*Penicillin
-orally*

Though frequently prescribed as an adjunct to parenteral therapy, Crystapen Oral Tablets are often adequate *alone* to overcome penicillin-sensitive infections in the early acute phase and are especially appropriate when the patient is a child.

CRYSTAPEN ORAL TABLETS

Trade mark

200,000 units crystalline sodium penicillin G per tablet:
tubes of 10, bottles of 100

NICORBIN TABLETS

Trade mark

riboflavine, aneurine hydrochloride, nicotinic acid and ascorbic acid:
bottles of 50 and 500

*4 Vitamins
-routinely*

The four water-soluble vitamins in Nicorbin are wisely administered *routinely* during treatment with the newer oral antibiotics (and even oral penicillin) to counter the sore tongue and other possible side effects of such treatment.

Research Laboratories

Manufacturers of medical products and foods

Agents or associated companies

in almost every country in the world

GLAXO LABORATORIES LIMITED, GREENFORD, MIDDLESEX, ENGLAND

SPACED ABSORPTION *of* CARBOHYDRATE

DALTOSE is a mixture of Dextrose, Dextrin and Maltose, fortified by the addition of Calcium Lactate and Vitamin D.

The Dextrose is immediately absorbed, and the Dextrin and Maltose are gradually converted to dextrose. As a result of this gradual conversion, there is spaced absorption of the sugars, with less risk of fermentation and of gastro-intestinal upset.

DALTOSE is used for modification of the infant's diet, and in the diet of the convalescent and of the geriatric patient as a source of extra calories.

Details of this product will be sent on request to the Medical and Research Department.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE BASIC PRINCIPLES OF ATOMIC STRUCTURE

BY

Sir JAMES WALTON, K.C.V.O., M.S., B.Sc., F.G.A.

Correspondence in the *British Medical Journal* and remarks made to me personally following the two papers on isotopes in medicine published in the *Journal* of September 29 have made it evident that many members of the medical profession have difficulty in understanding modern atomic physics. This is very understandable when it is realized how recent is the growth of this subject, so that there must be many general practitioners and specialists who learnt their physics in the days when an atom was only an atom. Now it is becoming essential that, with the progress of medical treatment, they should have an elementary knowledge of the underlying principles of atomic structure. The literature is, however, so immense and the many textbooks are often so large and highly technical that general practitioners have neither the time nor the opportunity to study them. It is my belief, nevertheless, that by omitting all mathematical considerations and the lines of reasoning that have led to the conclusions, and by concentrating upon the actual experimental findings and the accepted results, an elementary knowledge of the facts can be given very simply and briefly. It is true that such a method tends to be too dogmatic, in that certain conclusions which are still under discussion, or even not accepted by many, have to be stated as facts, but this is a privilege which is granted to all elementary teachers and may not be unduly harmful.

The Atomic Theory

About 500 years B.C. the Greek philosopher Leucippus taught that the ultimate constituents of all things were empty space and atoms, which were infinite in number, indivisible, and always in motion. About 100 years later Democritus, who is usually credited with the atomic theory, developed this view and taught that atoms were the ultimate material of all things and, although not visible, were heavy and impenetrable. These views, which were purely theoretical, were forgotten for some 2,200 years, when in 1804 Dalton announced his famous atomic theory, in which he showed that atoms could be defined as the smallest particles in which an element can exist, that they could not be broken up by chemical means, and that they possessed definite weights which could be expressed by numbers relative to the atomic weight of hydrogen, which is the lightest known element. Alternatively, they could be defined as the smallest part of an element which could enter into chemical combination with another element.

In 1864 John Newlands showed that if the elements were arranged in the order of their atomic weights there was a recurrence of similar chemical and physical characters at every eighth element. This he described as the "law of octaves." In 1869 Mendeléeff developed this idea more fully and published a table with the elements arranged according to his periodic law. Since then many new elements have been discovered, and

their insertion in the position of the table indicated by their atomic weights has confirmed his views and fulfilled his predictions.

Structure of Atoms

In 1897 Sir J. J. Thomson found that by passing an electric current through a glass tube filled with an attenuated gas of any variety (Fig. 1) a luminous ray was given off in a straight line from the cathode. This cathode

FIG. 1.—Sir J. J. Thomson's apparatus for generating cathode rays.

ray could be deflected by electric and magnetic fields in a direction showing that it was made up of negatively charged particles which are known as *electrons*. They have a speed of approximately $1/10$ that of light, produce luminescence when they impinge on certain substances, cause the leaves of an electroscope to diverge, and have considerable penetrating powers. Since they come from any gas, they must be a constituent of all atoms. The electrical charge which each electron carries is taken as the unit charge. They have been estimated to have a diameter of only 10^{-5} of a hydrogen atom and to weigh only $1/1,840$ of its nucleus.

The fact that negative particles are obtainable from atoms suggested that similar positive particles must be present, as atoms are electrically neutral. Goldstein was able to demonstrate their presence, and in 1898 Wren proved that they were positively charged. Mosely was able to show, by x-ray spectroscopy, the actual number of these particles, which are known as *protons* and are grouped together to form a *nucleus*. Since each contains a unit positive charge and the total atom is neutral, they must equal the number of electrons. Their number in each atom is known as the *atomic number* of that atom. They weigh approximately 1,840 times the weight of an electron. It is the number of the protons which determines the nature of the element. In hydrogen there is only one, in helium two, and so up the scale to uranium with 92. If the number of protons is altered, as occurs naturally in radioactive substances or can be brought about artificially, the element is changed to another.

The fact that the atomic number is less than the atomic weight, except in the case of hydrogen, made it evident that other heavy particles must be present, and in 1931 Sir James Chadwick discovered the presence of *neutrons*, which are in the nucleus and have a like weight to the protons, they and the protons forming nearly the whole of the weight of the atom. Neutrons have,

however, no electric charge, and their presence therefore does not affect the number of electrons and the chemical properties. They steadily increase in number with the atomic number but not in the same ratio; deuterium, or "heavy hydrogen," contains one, helium two, bromine 45, and uranium 146. Together with the protons they give the atomic weight of the element.

In 1885 a Swiss schoolmaster named Balmer discovered that there was a definite mathematical relationship between the positions of the lines seen in the spectrum of the light from glowing hydrogen. Based largely upon this knowledge and upon the later brilliant work of the late H. G. J. Mosely on the wavelengths of the x -ray spectra of the elements, the Danish physicist Niels Bohr was able in 1913 to evolve his famous model of the atom. He showed that it consisted of a heavy central nucleus around which the electrons moved in ellipses in any plane; the ellipses formed shells placed at

FIG. 2.—Diagrams showing the arrangement of the electrons in atoms of helium, neon, argon, beryllium, magnesium, chlorine, and zinc. The diagrams are purely schematic: the orbits or shells are much further apart, and they are in the form of ellipses, not circles; also they may lie in any plane.

distances corresponding to the square numbers 4, 9, 16, 25, 36, etc., from the nucleus, the numbers of electrons in each shell being fixed for each atom. Hence by far the greater part of an atom consists of empty space. In hydrogen there is only one shell containing one electron, but on passing down the periodic table the numbers gradually increase (Fig. 2), the number in the individual shells being 2, 8, 18, 32, 18, 12, 2, this being the arrangement of electrons found in uranium, the heaviest known element. Generally speaking the electrons are more loosely attached in the outer shells, so that the inner shells are filled first. The total number of electrons corresponds to the atomic number. The outer electrons are those which are concerned in chemical reactions, and it is found that those elements which have similar chemical characters—that is, which are in the same columns of the periodic table—have a similar number of electrons in their outer shells, thus confirming Mendeléeff's views in a remarkable manner.

Ionization and Electrolytes

Electrons may be displaced from the outer shell of an atom, and, being free, will soon become attached to other atoms of a similar or different nature. The atom from which an electron has been displaced will have lost one unit negative charge and hence will be positively charged. It is known as a *positive ion*, or, since it is attracted to the cathode, as a *cation*. In the same way the atom which has gained an electron is negatively charged and is known as a *negative ion*, or, since it is attracted to the anode, as an *anion*. Certain simple salts

when dissolved in water separate into ions, when they are known as *electrolytes*, and, as Faraday showed early in the nineteenth century, can be separated by the passage of an electric current, a process known as *electrolysis*. The passage of a high potential electric charge or of rapidly moving atomic particles through a gas will knock off electrons, causing the gas to become ionized and to become an electrical conductor. Certain resins have the power of attracting different ions and thus bringing about their separation. This process is to-day largely used commercially, but it has also its medical application (ion-exchange resins).

Isotopes

It had long been known that certain elements showed varieties which, although identical in every chemical and in most physical characters, had different atomic weights: for example, when uranium breaks down completely it is converted into lead of atomic weight 206. The actinium series in breaking down ends as lead with the atomic weight 207, and that derived from thorium has an atomic weight of 208, but all three are lead in every sense of the word. To these elements Soddy in 1913 gave the name *isotopes*. The differences in the

FIG. 3.—Diagrams of two isotopes of carbon, C^{12} and C^{14} .

atomic weights are due to the number of neutrons, and, since they have no charge, the number of electrons and hence the chemical characters are unchanged. Mass spectrography has shown that the majority of elements have isotopes (Fig. 3), and the fact that many atomic weights are not whole numbers—for example, magnesium 24.32, chlorine 35.457, tin 118.70—is known to be because they are mixtures of isotopes with different atomic weights. The nature of the isotope is usually shown by an index number giving its atomic weight—for example, C^{11} , C^{12} , C^{13} of carbon, or P^{31} , P^{32} of phosphorus. Sometimes the atomic number is also indicated—for example, $^{11}_6C$, $^{12}_6C$, or $^{31}_{15}P$, $^{32}_{15}P$. One isotope of hydrogen is of double the atomic weight owing to the presence of a neutron in the nucleus: it is known as deuterium, and its nucleus as a *deuteron*; a still heavier isotope is tritium, with two neutrons and an atomic weight of three.

What Prevents Spontaneous Atomic Explosion?

Physicists had long been puzzled over why the protons in the nucleus did not repel one another and the atom spontaneously explode. In 1934 Yukawa suggested that negatively charged particles would be found within the nucleus. They have since been discovered and are known as μ mesons. They have a unit negative charge like an electron and a mass between that of an electron and a proton. There are probably at least four varieties having from 200 to 1,000 times the weight of an electron. They are produced naturally by cosmic rays in the upper air,

are capable of penetrating 20 ft. (6 m.) of lead, and have only a short existence. They were believed to bind together the protons by a reaction known as exchange attraction, which occurs only in minute structures of atomic dimensions, so that if once the protons are separated by a short distance they repel one another with great force and the atom is disrupted. Later work (*vide* Sir John Cockcroft, *Nature*, 1951, 168, 1060) has shown that the Yukawa hypothesis is no longer tenable, as the μ mesons discovered by Anderson and Neddermeyer scarcely interact with nuclei, and in 1947 Powell discovered the π meson or pion, which may be positively charged, negatively charged, or neutral, the positively charged meson π^+ having a very short life (10^{-8} of a second) and changing into a μ meson. They have a mass about 275 times that of an electron. There is also evidence that there are even other and heavier mesons.

In 1932 Anderson and Blackett discovered yet another particle which is produced when cosmic rays are stopped by collision with a metal plate. These particles were found to be positively charged and were called *positrons*. They have since been obtained by bombarding aluminium with α rays, or lead with γ rays (see definitions below). They have a mass approximately that of an electron. They are probably formed by the nucleus absorbing the energy of a γ ray and converting it into a positron and an electron. The life of a positron is very short—about 10^{-9} seconds in the air. It then disappears completely, probably by combining with another electron and being entirely converted into energy as a γ ray, thus supporting Einstein's contention that energy and matter are interchangeable.

An atom therefore consists of a compact nucleus in which is centred by far the greater weight and which contains positively charged protons and positrons, negatively charged mesons, and neutrons with no charge. The number of protons determines the nature of the element, and the combined weight of the protons and neutrons gives the atomic weight. Surrounding the nucleus at relatively great distances are a number of electrons, corresponding to the number of protons, moving in various planes in definitely placed elliptical shells around the nucleus. They are concerned with chemical changes only. The smaller atoms are estimated to be about 2×10^{-8} to 6×10^{-8} of a centimetre in diameter and the electron to be only 10^{-10} of the diameter of the atom of hydrogen in its normal state.

Radioactivity

In 1896, a year after Roentgen discovered x rays, Becquerel showed that a uranium salt gave off rays capable of affecting photographic plates. Further investigation has shown that these rays are of three sorts.

α Rays.—These are composed of the nuclei of helium—that is, of packets of two protons and two neutrons moving at great speed (2×10^9 cm. a second). They therefore contain two unit-positive charges but are deflected with difficulty. Because of their small mass they have but little penetrating power, but because of their high speed they tend to break up atoms in their path, leaving free ions and so ionizing the air.

β Rays.—These are electrons moving at prodigious speeds. They are easily deflected and are 100 times more penetrating than α rays.

γ Rays.—These are identical with x rays, and consist of electromagnetic waves with no mass. They have very short wavelengths, about 0.005 Å, are extremely penetrating, and cause slight ionization, photographic, and fluorescent effects.

In searching for the source of these rays, the two Curies in 1898 extracted from pitchblende a number of radioactive substances, including radium, the most active of all. In 1902 Lord Rutherford showed that the emission of the rays was due to atomic disintegration, and that the seat of instability was the nucleus. It is the heavier atoms which show radioactivity, and it is present in all atoms with a higher atomic weight than bismuth. It would seem that nuclei containing large numbers of protons and neutrons are unstable. It is possible, therefore, that in the past there were elements of a higher atomic weight than those now known, but that they have completely degenerated.

Transmutation of Elements

In 1919 Rutherford exposed nitrogen to radium so that it was bombarded with α rays, and was able to convert some of the nitrogen into O^{17} , an isotope of oxygen, thus:

In 1932 Cockcroft and Walton were able to accelerate protons by very high voltages, and by their use were able to convert an isotope of lithium, Li^7 , into two α particles, thus:

By bombarding the isotope Li^6 with deuterons, a similar result was obtained:

but if Li^7 was bombarded with deuterons a neutron was also produced. It is reactions of this sort which are the basis of the hydrogen bomb. To-day large numbers of rapidly moving charged particles may be directed upon elements by the use of the cyclotron. This is a large and powerful machine consisting essentially of two electrodes for producing ions, and a high-frequency oscillating electromagnetic field for repeatedly accelerating the ions as they travel in an ever-widening flat spiral. After about a hundred revolutions the ions are drawn off their spiral track into a bombardment chamber, where they may be used to produce neutrons or electrically charged particles such as protons, mesons, and, to a lesser degree, electrons. The neutrons can be used to make radioactive isotopes artificially, but this is usually now done in an atomic pile (see below).

By these means, elements may be bombarded with protons, α particles, deuterons, or neutrons. When protons meet other nuclei the result will depend upon their energy resonance. If less than that of the nucleus they will bound off. If of similar resonance they will enter it and form a new element of greater atomic weight. In this way two new elements—neptunium and plutonium, both of atomic weight 239 but with atomic numbers of 93 and 94—have been formed. If of a higher resonance they will split up the nucleus, often with explosive force. Neutrons have similar effects, but if they enter the nucleus they form not new elements but isotopes, many of which are unstable and radioactive.

The Chain Reaction

The explosive effect of these bombardments may occur naturally, as in U^{235} . Here protons and neutrons driven off from one atom will explode the next atom, the so-called chain reaction. If the mass is sufficiently large (critical mass) to prevent the escape of the protons and neutrons the whole mass will explode with enormous violence and heat, as in the atomic bomb. The chain

reaction may be controlled, and the enormous energy utilized, by slowing down the protons and neutrons by passing them through material of low atomic weight, such as deuterium or graphite. This is the basis of the atomic pile.

Isotopes in Medicine

The isotopes prepared by these methods now number over 700, and, since many are radioactive, they are being used to an increasing degree in medicine. They are used either for treatment, by giving a radioactive element which may have a therapeutic effect, as upon a cancer with an affinity for the element—for example, the isotopes of iodine, I^{128} or I^{131} , for the treatment of some varieties of carcinoma of the thyroid—or to trace the metabolism of an element (or a compound containing it) in the body—for example, phosphorus by its isotope P^{32} . Their use may, however, be associated with danger, for, if their breaking-down period is long, the radioactivity may be carcinogenic rather than curative. Fortunately in the artificial isotopes the period to half-way disintegration (half-life) is usually short; according

FIG. 4.—Diagram of a Geiger counter.

to Wormal, for the isotopes of iodine and phosphorus it is 8 and 13 days and 14.3 days respectively. This is in marked contrast with uranium, for which it is about 500 million years.

The position in which the isotope is concentrated can be readily determined, if it is radioactive, by the use of the *Geiger counter* (Fig. 4). This consists essentially of a glass tube down the centre of which passes a fine tantalum wire. The centre of the wire is surrounded by a cylinder of thin copper, and the tube contains gas under a reduced pressure, usually argon and ethyl alcohol. The wire is positively charged and the cylinder negatively charged, with a maintained difference of potential such that a discharge will just not pass between them. If a fast-moving electron, proton, α particle, or even a photon of light passes between them, the gas is ionized and a momentary current will pass between the tantalum and copper. This minute rush of current is amplified by radio methods and emitted by a loudspeaker so that it is audible to a number of people standing around. The number of cracks or thumps may be counted or automatically recorded so that the radioactivity can be estimated. Saunders states that the instrument is so delicate that a match lit on the other side of the room gives a rush of such cracks.

"Music while you work" was one of the successful British ideas of wartime which was exported across the Atlantic. In one New York insurance company, employing thousands of clerks and machine operators, efficiency has been raised 19% since the provision of music over the hum of routine work. In department stores suitable music will make the customer linger at the cosmetic or hosiery counter and make a further purchase. And now dentists are offering patients music by headphone to distract them from the noise and vibration of the drill, while those undergoing plastic surgery under local analgesia are also thus diverted.

Reports of Societies

CORTISONE AND A.C.T.H. IN GENERAL PRACTICE

A meeting of the General Practice Section of the Royal Society of Medicine was held at No. 1, Wimpole Street, on December 19, 1951.

Dr. A. TALBOT ROGERS, who opened the discussion on "The Possible Future Use of Cortisone and A.C.T.H. in General Practice," described himself as a general practitioner with a special interest in rheumatic diseases. Being in charge of the physical medicine department of his local hospital, he had had the advantage of co-operating with Dr. E. N. Allott in his work on cortisone and A.C.T.H. (adrenocorticotrophic hormone) at Lewisham. He wanted to emphasize the words *possible* and *future* in the title of the discussion because he felt that there was not much hope that these substances would become widely available in the near future or that the cost of maintaining a rheumatic patient on either of them would soon be diminished from the present level of £10 to £20 a month. Because of this it was right that the supply of cortisone and A.C.T.H. should be limited to research centres; yet general practitioners should know about this type of treatment, as they would be responsible for sending the right type of patient for treatment and for helping to maintain treatment after discharge.

In a brief review of the scientific background of the subject Dr. Talbot Rogers recalled that the pituitary gland was under nervous control and when stimulated by bodily stress released varying amounts of A.C.T.H.; this in turn stimulated the adrenal cortex to produce its many hormones affecting salt and water metabolism, sugar and glycogen, protein metabolism and androgenic activity, in addition to cortisone. The diseases in which A.C.T.H. and cortisone could be used included rheumatoid arthritis and Still's disease: in these two diseases they offered the first really spectacular advance in therapy. In spondylitis deformans he had not experienced such a well-marked response, and, although this had been claimed by some American workers, he felt that this discrepancy was due to disagreement on what constituted spondylitis deformans. Of their activity in rheumatic fever he gave a guarded account, saying that, although they abolished symptoms and seemed to protect the heart, their effect was not yet certain. However, this was an excellent short-term use for cortisone, because the disease process eventually died out and indefinite maintenance doses were not necessary. Other diseases that benefited were acute lupus erythematosus, status asthmaticus, some cases of haemolytic anaemia, periarteritis nodosa, many eye conditions, exfoliative dermatitis, pemphigus, severe burns, and ulcerative colitis.

The Dangers

It was important that the general practitioner should know the complications that might arise from treatment with cortisone or A.C.T.H. The greatest danger with both was that they delayed healing, a serious matter with peptic ulcer or with active or recent pulmonary tuberculosis; septic conditions were masked and tended to spread silently without the usual pain and reddening—they could be detected only by increased swelling and a general rise of temperature. Because A.C.T.H. produced a general secretion of cortical hormones it was liable to produce disturbances in salt and water metabolism, with rise of blood pressure which was particularly dangerous in patients with heart disease. Diabetes could be precipitated and diverse psychotic changes could result—euphoria proceeding to mania or depression and insomnia. Cushing's syndrome was also liable to appear, with the characteristic "moon-face," hirsutism, amenorrhoea, acne, ecchymoses, flattening of the neck, and humping of the back and abdomen with deposits of fat.

A view of the Chloromycetin plant and Research Unit at the Parke-Davis Laboratories, Hounslow

A New Era . . .

The synthesis of Chloromycetin in the Parke-Davis Research Laboratories and its subsequent production on a large-scale manufacturing basis by a synthetic process marked the beginning of a new era in chemotherapy. Now that this life-saving drug is freely available, clinicians throughout the world are acclaiming its success in an impressive range of infections. Many previously intractable conditions can now be controlled by this single therapeutic agent.

Chloromycetin

The problem was to provide soluble aspirin in stable tablet form

The therapeutic advantages of the calcium salt
of aspirin over aspirin itself have been repeatedly
stressed in the medical literature.

Being an acid substance of
low solubility, aspirin may act
as a gastric irritant.

By contrast, calcium aspirin is neutral and highly
soluble. Calcium aspirin, however, has its own defects.
It is an unstable compound, and its presentation in
stable and palatable form has challenged research
workers for many years.

The difficult problem of the preparation of calcium
aspirin in stable and palatable form has at last been
solved in 'Solprin'.

Solprin has all the valuable properties of aspirin —
analgesic, antipyretic and anti-rheumatic and, being
soluble, it is more rapidly absorbed and consequently
more speedy in its therapeutic effect. Thus Solprin
embodies the virtues both of aspirin and of calcium
aspirin without certain defects which hitherto have
restricted the usefulness of these two preparations.
Solprin rapidly dissolves in water to yield a solution
of calcium aspirin, which is substantially neutral,
stable and palatable.

S O L P R I N REGD.

Stable, soluble, palatable calcium aspirin

Clinical sample and literature supplied on application. Solprin is not advertised to the public and is available only on prescription. (U.K. and Northern Ireland only.) It is not subject to Purchase Tax, and when prescribed costs actually less than 1d. for three tablets.

BECKITT & COLMAN LTD., HULL AND LONDON. (PHARMACEUTICAL DEPT., HULL)

In this country both drugs were usually given by injection; this, he felt, was a good thing, because one could seldom trust the patient to take the drug by mouth as regularly as seemed necessary for maintenance. Withdrawal symptoms were serious, and slight changes in the regularity of dosage, especially with A.C.T.H., might well produce serious symptoms. The supplies were so low to-day that the criterion by which the patient should be treated should be his ability to move and work and not be a burden on his family rather than the state of his joints, which, at a dosage graded to keep him at work and avoid complications, might still give pain.

Dr. W. S. C. COPEMAN said that Kendall had isolated 26 different steroid substances from the adrenal cortex, one of which was cortisone. The administration of A.C.T.H. to a patient stimulated the production of all 26, and more side-effects might therefore be expected than after cortisone alone. Although the disease process of rheumatoid arthritis and Still's disease could temporarily be completely reversed, these drugs did not produce a cure, and the patient generally relapsed to his previous condition when treatment was discontinued. In diseases of the eye there was scope for short-term therapy, and in status asthmaticus a single treatment could be life-saving.

Selection of Cases for Treatment

The supply of cortisone might well increase in the near future; at the moment the drug was partially synthesized from ox-bile as a starting product. Another starting product derived from vegetable sources was being investigated, but, although if successful the new process would make cortisone more plentiful, it was unlikely to become appreciably cheaper owing to the complexity of the process involved. Although some patients were able to get a limited supply for themselves from abroad, he was never prepared to treat any that had less than a six months' supply: the mental effect of reverting to their original condition after a short space of freedom was so grave as not to justify a short period of treatment without there being some special reason for this.

Patients suitable for treatment should be selected carefully. The unstable personality was liable to develop a psychosis, and the patient with permanently damaged or ankylosed joints could not expect relief. It did not seem to be necessarily the early case that yielded the best result, since such cases might be at their most active stage and require heavy and prolonged dosage; an old-established case without excessive joint damage often responded better, and might go into remission. The cardiac and the hypertensive patient were unsuitable and renal disease was a contraindication. He had seen one case of insulin-resistant diabetes develop. Gastric ulcers could perforate and herniae strangulate silently without marked symptoms or signs.

Treatment should always be started in hospital, where the patient's characteristics of weight, blood pressure, and water balance should be established and the blood count (especially the eosinophils) and sedimentation rate recorded. The electrocardiograph was useful as a guide to potassium loss, since the blood level was sometimes fallacious. When the patient then returned to the care of the general practitioner the complications that Dr. Talbot Rogers had outlined should be looked for, and also undue fatigue, alkalosis, and osteoporosis, which might be the cause of spontaneous fractures. In patients under treatment pains in bones and joints were probably more often caused by their unaccustomed use than by insufficient control of the disease, and seldom called for increased dosage. To avoid withdrawal symptoms the dose should always be decreased very slowly indeed.

Clinical Results

Of the series of 20 patients with rheumatoid arthritis that Dr. Copeman and his group had selected, in conjunction with the Medical Research Council, for testing the long-term activity of cortisone, after nine months 17 were com-

fortable and all the men were at work and most of the women doing part-time housework. Only one case had gone into remission; one had developed symptoms of toxicity, and his treatment had been discontinued but later resumed without further ill effects. Dr. Copeman said that cortisone and A.C.T.H. were not a cure for rheumatoid arthritis and had in no way superseded the older methods of treating the disease. They were, however, an important adjunct to treatment in certain cases; above all they were potent "research tools."

Dr. E. N. ALLOTT said that the group of workers at Lewisham was trying to find the minimum doses necessary for treating and maintaining patients. Such was the expense of cortisone that, although an expenditure of £75 to £100 a year might be sufficient in some cases to keep a patient at work, £150 to £200 would often be needed to keep him free of pain and discomfort. Half their supplies had to be set aside for maintaining old patients, and that greatly limited the number of new cases they could take on. Besides the rheumatic diseases, disseminated lupus erythematosus and discoid lupus of the skin had shown great improvement, but both had required maintenance treatment. Polyarteritis nodosa had not responded well; that might be due to insufficiently early diagnosis. One case of scleroderma had made a slight improvement. Two cases of asthma and four of burns had responded well. Cases of leukaemia, agranulocytosis, aplastic anaemia, and nephrosis had not been affected. The results in haemolytic anaemias were hard to assess, but one case of refractory macrocytic anaemia had been improved and had not required maintenance treatment. A case of exfoliative dermatitis had responded well at first, but the disease had become resistant although a gross Cushing's syndrome had been produced by the treatment.

Laboratory Control of Treatment

Cortisone could be given by mouth or by injection every other day or every three days. A.C.T.H. had usually to be given four times a day; the effect of the same amount of material was increased if given more frequently. Of the laboratory tests for controlling treatment, the eosinophil test was unreliable. The blood sedimentation rate was of little value, because only when full doses were given was it decreased; with maintenance doses of the usual size it generally remained as high as in the active disease. 17-ketosteroid excretion was of little use, and blood electrolyte determinations were of limited value. The best control was general clinical observation; electrocardiography was useful for detecting potassium deficiency.

More Clinical Results

Dr. D. BRIGGS (American Hospital of Paris, Neuilly-sur-Seine, France) gave his experience of patients whose treatment was determined by their ability to pay for the drugs rather than by whether they were suitable for treatment; these included nine cases of rheumatoid arthritis. All had responded to cortisone, but one deteriorated with A.C.T.H. One case of Reiter's syndrome had been treated for two months when remission occurred. Cases of status asthmaticus had been cured, but when pulmonary fibrosis formed the basis of the asthmatic condition there had been no response. Various other cases were described. As side-effects he had observed the formation of abscesses in two patients; one of these patients had become drowsy on withdrawal of the drug, and this had been ascribed to sodium loss.

Status Asthmaticus

Dr. K. ROBERTSON (Southampton) confirmed the experience of other speakers about the usefulness of cortisone in status asthmaticus, considerable remissions following one or two doses given during the acute emergency. He hoped that cortisone would be made available for the use of general practitioners faced by that most troublesome and alarming syndrome. He referred too to a dramatic response to cortisone in a colleague with a very severe allergic reaction to

the experimental injection of a staphylococcal antigen, and reported immediate resolution of severe stomal ulceration when A.C.T.H. was given by the slow intravenous drip method. In a case of chronic lymphatic leukaemia, cortisone by mouth had on two occasions produced a striking reduction in size of the enlarged lymph nodes and spleen, though the blood picture had not been influenced. In two cases of what appeared to be irreversible peripheral failure in diabetic acidosis, following the control of hyperglycaemia and biochemical correction of electrolyte disturbance, cortisone had appeared to be life-saving.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Malaria

SIR,—I was much interested in the letters of Colonel L. W. Harrison and Sir Philip Manson-Bahr (December 8, 1951, pp. 1402-3). For anyone to apply to the former the epithet "has been," which he fancied he invited, is merely to emphasize the ignorance of the applier; while the authority of the latter on all questions of tropical and sub-tropical diseases is unchallenged. It is therefore with no little reluctance that I venture to differ from each of them.

In the first place I do not think that the life-saving properties of quinine by injection can seriously be doubted: it is the method of injection which is open to challenge. A long time has passed since the unfortunate "tetanus episode" reported by Semple as a sequel to the intramuscular injection of quinine; and in modern conditions, in the Indian subcontinent at any rate, this sequela should no longer be a bogey. Injectable quinine solutions have long been marketed by many reputable pharmaceutical firms in ampoule form, and these form part of the stock of the great majority even of outlying dispensaries in India, while hospitals of any size are equipped with autoclaves, which should effectively deal with any tetanus spores if it were found necessary to prepare a home-made solution.

The objection—and I venture to think a very valid one—to the intramuscular injection of quinine rests nowadays not on the fear of tetanus but on the confirmed observations of Acton and Chopra (*Indian J. Med. Res.*, 1924, 12, 251), Karamchandani (*Rec. Mal. Surv. Ind.*, 1933, 3, 445) and others, that necrosis of the tissues invariably accompanies this procedure. This objection, however, is not applicable to the intravenous injection of the drug; and, this being the case, there would appear to be little or no justification for the selection of the intramuscular route in cases—and they form the great majority—in which the vein is accessible and in which parenteral administration is called for as a life-saving measure. There are, of course, exceptions such as stout women with small veins, and infants and young children, but even in these cases diligent search will often reveal an accessible vein. Accordingly, it was my personal practice in any hospital of which I was in charge to prohibit the intramuscular injection of quinine except in those cases which I or, in my absence, my locumtenent personally sanctioned; and I venture to think that such a course has much to be said for it.

It is to be remembered that the vast majority of cases of malaria are treated not by eminent specialists but by medical subordinates who cannot be expected to have the experience, judgment, or responsibility of the pundits. The effect of the authoritative blessing of the intramuscular route has, to my knowledge, been to encourage the lazy practitioner who is averse from taking the trouble to ensure the proper administration and retention of quinine by the mouth and indulges instead in pincushion therapeutics. Anyone who has seen for himself the crop of painful nodules persisting

for months and years resulting from this lazy and pernicious practice cannot fail to have strong views. In one case which I have been able to follow nodules and pain have now persisted for over 10 years. For this reason alone the supersession of quinine by the synthetic antimalarials for oral administration is devoutly to be welcomed.—I am, etc.,

Commonwealth Relations Office, S.W.1.

J. B. HANCE.

Humid Climate and Respiratory Diseases

SIR,—I shall be grateful if you will grant me space in your columns to remark on the view, which appears to be held by many doctors, that a warm, humid climate is beneficial to those suffering from respiratory diseases.

For the last five years I have experienced the pleasures and frustrations of practising medicine in Nassau, in the Bahamas. During my first winter here the incidence of respiratory affections, notably asthma, struck me as being excessive. In the following spring and summer I made the same observation concerning hay fever. Later experience here has confirmed both observations. The increased incidence of these affections appears to be directly related to the excessive humidity of the climate, which averages between 70-80% in the winter months and between 80-90% in the summer months. Occasionally during winter a relatively cold north-westerly wind blows for a short period—often less than 24 hours. One of these winds is always followed by a crop of asthmatic attacks. During the summer there is a long period of relative drought, but the humidity remains very high. The dust and pollens from the bush which abounds everywhere undoubtedly play a part in the high incidence of hay fever during the dry period.

Comment on these factors and respiratory diseases has already been made by Dr. W. Santon Gilmour, in his able survey of tuberculosis in the Bahamas. Unfortunately this publication is probably not available to the general medical public. From time to time I have met professionally and in a private capacity individuals who have been sent here to a warm climate for the benefit of a respiratory condition such as asthma, chronic bronchitis, and bronchiectasis. Almost invariably these unfortunate persons have suffered a relapse, sometimes of extreme severity. Bermuda, Jamaica, and other islands in this area appear to have as high an incidence of respiratory affections as we have here. It appears to me, therefore, that the attention of practitioners should be drawn to the fact that a warm, humid climate will probably do their patients more harm than good, no matter how beneficial a warm dry climate may be.—I am, etc.,

Nassau, Bahamas.

W. H. P. POAD.

Sexual Disorders in Women

SIR,—Dr. Joan Malleison's article (December 22, 1951, p. 1480) would be timely even if only a fraction of her figures for frigidity and partial frigidity were true; though I think to some extent we are dealing with a cultural phenomenon, as well as individual maladjustment.

In psychiatric out-patient clinics I can only say that without special psychological presuppositions one comes across sexual difficulties so frequently that on the whole one only attempts to pursue those where their emergence is comparatively recent, the distress marked, and the patient of reasonable intelligence. This frequency is more understandable if one gives a large place in the total personality to the sexual drives; but in any case the adequate expression of them in the face of our culture remains more difficult for a woman than a man. There are, of course, also cases, such as depressions, where the lack of sexual feeling is only part of a general emotional disturbance. Those cases who have the insight and determination to complain frankly of their difficulties are more accessible, but not necessarily in less trouble, than those who complain of anything but their sexual difficulties. I have not always found that the hysterical anaesthesias are comparatively harmless, except perhaps on a short-term basis. In my cases, though, a picture of pure hysteria without some leakage of anxiety is not very common.

I think Dr. Malleon merits the fullest support in her attitude to clitoral orgasm. I have not found, though, that prudery is always the difficulty. The woman may feel, perhaps unnecessarily, that it all becomes a very planned affair, and as such underlines her inadequacy: she fears either losing sensation further, or reaching a high state of stimulation and then being unable to achieve orgasm. Much complicated emotional reaction may be implied in such an acceptance, and much here depends on the wife's feelings, not necessarily bad ones, to her husband, and his to her.

There is no doubt room for the various approaches of the gynaecologist, physician, surgeon, and psychotherapist, inspired, I hope, with humanity. These problems rarely stay individual for long, even if they were ever so in their general significance. Almost invariably a vicious circle of tension arises between wife and husband. Frequently one sexually maladjusted partner picks another, and what might be a minor difficulty becomes magnified out of all proportion. I feel, therefore, that an attitude of joint responsibility on the problem needs encouraging, and it is not only wise but accurate to avoid laying too much of the responsibility on one side.

The psychotherapy to be used needs definition. Some cases which are the result of deep maladaptation of personality are really only approachable by long-term analysis, and this is a very large undertaking. Others, especially the more superficial type, are treatable by the therapy of discussion, explanation, and support, admittedly often implying analytic interpretation, with or without physical and pharmaceutical aids—largely, I find, sedatives. In my experience the apparently most discouraging case does not always turn out to be so. In the shorter methods the patient cannot gain insight in the same way as by analysis, but in sexual matters the lack of voluntary control puts morale at a premium, and success with support may allow a patient to achieve more mature attitudes, which are also the long-term object of deep analysis. By this I do not imply any devaluation of analysis as a weapon of exploration, but only that for many patients a saving of money, but especially of time at such a crisis, may be crucial.—I am, etc.,

London, W.1.

H. A. C. MASON.

SIR,—I think that Dr. Joan Malleon's article on this subject (December 22, 1951, p. 1480) is of considerable service, because this matter is not only imperfectly understood but very largely unrecognized, even in the profession of medicine, and there must be many practitioners who are not even aware of the separate existence of the clitoral and vaginal orgasm in woman. It is most certainly true to say that a large number of women never experience a vaginal orgasm at all, and if they are unaware—as many are—of its existence there is no worry attached to this fact; the worry comes from the absence of any kind of orgasm during intercourse, particularly if it can be brought about at other times by the process of masturbation.

I agree with Dr. Malleon that where there is a failure of orgasm in the presence of a repeatedly high-pitched erotic tension nervous symptoms will ensue, but in my experience these symptoms point to disturbances which cannot be explained without real knowledge of the woman, her life, and her personality. Anaesthesia is a satisfactory surface explanation, but it does not get us anywhere; its possible hysterical origin is a much more fruitful field, and is, in my experience, the root difficulty and supplies the reason why this anaesthesia is less amenable to therapy than are the other dysfunctions; it also provides the reason why those functional sexual disorders which are secondary to adult events are much more likely—indeed almost certain if handled rightly—to resolve.

If we assume that this anaesthesia is a hysterical conversion symptom and accept that its origin lies invariably in the repression of early infant sensations we are going to find it very difficult to deal with; if, on the other hand,

we regard the conversion symptom as protective against an existing difficulty—that is, flight-reaction or negative response towards it—we shall succeed, provided that we can remove the circumstance or difficulty which has aroused the need for protection. But there is another factor which, in my experience, is of the utmost importance: it has been said—and I myself have no doubt of the truth of this—that in the true entity of hysteria there is an alteration in the ratio of the sex in the psyche. This would mean that the hysterical woman would possess a higher ratio of male to female in her personality, a state of things somewhat hostile to satisfactory sex relationship in so much as she will find it difficult to assume the passive role, *not* in the physical but in the emotional sphere. The markedly hysterical woman is, as I see her, utterly feminine to look upon but the very opposite as we search deeply into her. She can, and she often will, obtain a vaginal orgasm in sleep. She will wake with this to find the process continuing until it has exhausted itself in the usual way. If this should happen she will be disturbed, and she will search for the reason; she may even set out to test a new-found theory by an excursion into extra-marital relationship which, if it should succeed in producing this same orgasm, would be a disaster greater than the first, though for the time being she will have found a most satisfying "cure."

It is, of course, essential that a high pitch of erotic tension together with its accompanying tumescence should be relieved and especially so if it is often repeated, and I note Dr. Malleon's reference to the woman who, unable to obtain a vaginal orgasm, deprives herself of the relief of a clitoral one. She draws attention to possible thoughts of propriety and to the feeling that this is "all wrong," or "not natural," a view which I would say is as often, if not more often, shared by the husband. Dr. Malleon says that "a little sensible information on the matter can make a tremendous difference to some women." I would emphasize the word "some," for things do not always work out that way. A congestion may well be brought about by the husband, but there are numerous cases in which only the woman can do this for herself; and these are the difficult cases, because it may well be that the husband is not the partner, as it were, in the emotional side of the union. Equally difficult, though in a different way, are those cases in which neither the husband nor the wife is able, by any means known to them, to bring about the much needed relief to congested pelvic organs.—I am, etc.,

Westham, Pevensy.

MAURICE L. YOUNG.

SIR,—Dr. Joan Malleon's paper (December 22, 1951, p. 1480) must have been read with much interest and relief by practitioners whose medical education dates from pre-Freudian days. But even those who have accepted his teachings may not always derive from them the enlightenment and inspiration needed when dealing with those vexed cases of female orgasm inability. This is due to the fact that in these matters we are not without prejudice and that our conception of what constitutes a normal woman is still far too much influenced by memories of the times when, in matters of sex, woman was regarded as a kind of man in disguise. Very slowly only does the knowledge spread that a woman's sexual life history coincides nowhere with that of a man, that sexual reactions and manifestations normal to him may by no means be normal to her, and that we must investigate and judge her normality by purely female and not by male standards.

We might have wasted much less of our time and we might have avoided giving much misguided advice to our patients if, while investigating the orgasm riddle, we had not so deplorably lost sight of the biological aspect of the matter. A survey of the animal kingdom shows that in the majority of species, where the males are endowed with very efficient genital and extragenital organs of copulatory fixation, the active participation of the female is, teleologically speaking, unnecessary and in fact absent. In those

few species where neither genital nor extragenital organs of fixation have developed, the females do in fact participate, thereby facilitating fertilization. The present-day human race presumably finds itself midway between the anthropoid ape stage, where the female is solely an object of the male's sexual desire, and the human stage, where coitus takes place by mutual consent only. Always assuming that the object of sexual relations is fertilization and the survival of the race, neither the conditions prevailing on the sub-human nor those on the human plane seem to necessitate the development of female orgasmic ability, and it is not so surprising therefore that this trait presents itself as something that might be as well on its way in as on its way out (Terman).

For practical purposes meanwhile we must remember that in all women orgasmic ability is not, as in the male, a necessary, well-established sensation but a *noli me tangere*, capable of manifesting itself fully in ideal circumstances, partially on less auspicious occasions, and of remaining totally in abeyance if inhibited by one of the thousand causes so well known to psychologists. Only where we can remove all of them—and wherever we can we do that—may we expect a woman to display her full capacity. For the rest we must continue to remind her that the acme of her sex life and the source of the most intense and lasting pleasure are not to be looked for in coital activity but in the birth of her baby.—I am, etc.,

Pinner, Middlesex.

EDWARD ELKAN.

Male Infertility

SIR,—I wish to draw attention to your leading article on this subject (December 22, 1951, p. 1507) and especially to the passage, "Some clinics find it difficult to persuade the husband to attend for interview or even to provide a seminal specimen."

I would remind you that the question of providing a seminal specimen is one of grave difficulty for Roman Catholics. The usual method of providing a seminal specimen is either by the use of a condom during sexual intercourse or by ejaculation into a condom or other vessel during masturbation or coitus interruptus. These methods are regarded by all Roman Catholics as perversions of nature and hence as intrinsically evil, and their use would be a grave sin. Since the question of sterility is a serious problem to many Catholic couples, I would urge that greater use be made of such methods of estimating male fertility as testicular biopsy and the excretion of gonadotrophins and androgens in the urine, which do not involve the committing of offences against the natural law.—I am, etc.,

Manchester, 12.

F. N. VALDEZ.

Cerebral Blood Vessels and "Priscol"

SIR,—Recently (October 13, p. 891) Drs. S. Smith and E. C. Turton reported a case in which motor aphasia and agaphia were temporarily relieved by intravenous and oral "priscol." The authors attributed the therapeutic effects of the drug to its vasodilatory action in the affected area of the brain. In view of their statement that, "although many papers have emphasized the value of priscol in peripheral vascular states, none has been concerned with the effect of the drug on the cerebrovascular system," I wish to draw attention to some experiments of mine which confirm their clinical observation and their explanatory comment.

A window was made into the skull of adult cats under "nembutal" anaesthesia and pictures were taken through a capillary microscope before and after intravenous injection of 5-mg. priscol (technique to be described in detail elsewhere). In all ten experiments a prompt dilatation of the pial arteries and arterioles was observed, lasting up to seven minutes. The duration of the vasodilatation was not followed longer, the animals being used for another experiment. The veins were not noticeably dilated. Priscol had a vasodilatory effect also in cases in which vasospasm was produced by concussion. The effect is shown in the Figures. Fig. 1 was taken before, and Fig. 2 seven minutes

FIG. 1.

FIG. 2.

"a" represents an artery, "v" a vein.

after, intravenous injection of 5 mg. priscol. The results of these experiments, performed in 1941, were mentioned in a recent article (Engel, *Acta psychiat., Kbh.*, 1950, 25, 153): "A drug which, as far as I know, has not been tried out in cerebral vascular affections of spastic nature is priscol. . . . I tested its effect on cerebral blood vessels by capillary microscopy through a window in the skull of cats, and found it to be a powerful vasodilator. . . ."

I am convinced, judging from Smith and Turton's report and my experiments, that in suitable cases priscol may have a salutary effect on the cerebral blood circulation. A trial should be given to it in cases of post-concussional syndrome, 5-6 weeks after trauma, in migraine, and in any vasospastic conditions in which no danger of cerebral haemorrhage exists. It may also be indicated in primary shock. The reduced blood pressure following injection might be an advantage.—I am, etc.,

Hong Kong.

D. ENGEL.

L-Noradrenaline as a Vasoconstrictor

SIR,—Some remarks on the blood pressure effects of D-methyl amphetamine ("methedrine") in Dr. H. C. Churchill-Davidson's most interesting paper (December 29, 1951, p. 1551) must be called in question. He states that L-noradrenaline produces an almost similar rise of systolic and diastolic pressures, while methedrine produces only a slight rise of diastolic pressure in comparison with the systolic elevation. My experience with methedrine for correcting the hypotension accompanying high spinal blockade is not in accordance with this assertion.

In 300 cases under controlled hypotension intravenous methedrine has produced a diastolic rise of the order of slightly more than half the systolic rise. This is comparable with the systolic/diastolic pressure ratio obtained with noradrenaline in Dr. Churchill-Davidson's data. I have measured the pressure rises shown in his charts in response to ten separate administrations of noradrenaline, and compared them with the responses obtained from methedrine in a random sample of ten cases rendered hypotensive by high epidural block. The results are shown in mm. Hg:

Response to Noradrenaline. (Dr. H. C. Churchill-Davidson)

Data	Fig. 2	Fig. 3	Fig. 4					
Systolic rise ..	25 53	68 300	74	65	65	71	90	38
Diastolic „ ..	18 30	30 155	75	30	40	20	58	35
State	Haemorrhagic hypotension		Ganglion-blockade hypotension					

Response to L-Methyl Amphetamine (Methedrine)

Dose of methedrine in mg.	5	5	6	6	5	6	6	7	4	6
Systolic rise	40	50	35	45	55	35	35	65	35	35
Diastolic	35	35	20	25	45	30	20	30	25	20
State	Spinal block vascular hypotension									

It can be seen that in the figures from Dr. Churchill-Davidson's charts the diastolic rise averages 55.7% of the systolic rise in

A new advance in the chemotherapy of tuberculosis

The value of P.A.S. in certain stages of tuberculosis is now accepted. The drug is, however, very rapidly excreted, and continued medication at intervals of 2-3 hours is essential if the necessary blood titre is to be maintained. Administration in the form of 'Enseals' brand timed disintegrating tablets offers the following advantages.

- **ABSENCE OF GASTRIC SYMPTOMS.** Ensures that the full amount needed will be taken. The patient is not tempted to miss occasional doses.
- **HIGHER CONCENTRATION.** Each tablet contains 0.5 Gm. para-aminosalicylic acid, equivalent to 0.69 Gm. of hydrated sodium P.A.S.
- **THERAPEUTIC LEVEL MAINTAINED.** The delayed action of 'Enseals' can be made use of to keep up the blood level during the night, when it normally falls almost to zero. (Dosage schedule on request.)
- **'ENSEALS' ARE DIFFERENT.** Relying only on time and moisture for disintegration, their action is virtually independent of the pH of the small intestine.

'Enseals' brand timed disintegrating tablets each containing 0.5 Gm. para-aminosalicylic acid are supplied in bottles of 100, 1,000 and 5,000 (No. 69).

In Para-nasal infections **ARGYROL** provides physiological action without CNS stimulation or rebound congestion

● A return to normal function by the decongestive, demulcent and bacteriostatic actions of ARGYROL is achieved without the side effects and rebound so frequent with many vasoconstrictors. In the solution of para-nasal problems, the ultimate advantages of using ARGYROL are readily apparent.

The ARGYROL Technique

1. The nasal meatus . . . by 20 per cent ARGYROL instillations through the nasolacrimal duct.
2. The nasal passages . . . with 10 per cent ARGYROL solution in drops.
3. The nasal cavities . . . with 10 per cent ARGYROL by nasal tamponage.

Its Three-fold Effect

1. Decongests without irritation to the membrane and without ciliary injury.
2. Definitely bacteriostatic, yet non-toxic to tissue.
3. Stimulates secretion and cleanses, thereby enhancing Nature's own first line of defense.

There is no
chemical substitute for
ARGYROL

Argyrol can be prescribed
on N.H.S. form E.C.10

Decongestion and Relief without Rebound ● **Decongestion without Dysfunction**
— the medication of choice in treating para-nasal infection

*Argyrol is a registered trade mark, the property of the makers A. C. BARNES CO. NEW BRUNSWICK, N.J.

Sole distributors in U.K.:— **FASSETT & JOHNSON LTD. 86 CLERKENWELL RD., LONDON, E.C.1.**

EACH NERVE STRETCHED

From neurasthenia to neuralgia, from headache to migraine, rheumatism and dysmenorrhea; the gamut of conditions associated with

pain falls upon the fertile soil of a neurotic disposition. Veganin* has been designed to bring about a prompt assault upon a revolt of nerves, and many mystifying nervous complaints surrender promptly when its sedative and analgesic treatment is brought to bear.

Veganin is an original product of constant high standard, guaranteed purity and proved reliability; it has never been advertised to the public and is available for prescription under N.H.S. rules: when so prescribed it is illegal to substitute any product for Veganin.

FORMULA. Each table, 11.8 grs., contains:—w/w Acid Acetylsalicyl. 32.68%. Phenacet. 32.68%. Codeine 0.99%. Excipient ad. 100.00%.

VEGANIN

TRADE MARK REG.

Supplied in tubes of 10 and 20 tablets. Also available in bulk packages of 100 and 500 for dispensing only. Not subject to Purchase Tax when used on prescription.

NO WARNER PREPARATION HAS EVER BEEN ADVERTISED TO THE PUBLIC

William R. WARNER and Co., Ltd., Power Road, London, W. 4.

response to *noradrenaline*, while my figures for *methedrine* show an even greater diastolic response, averaging 61.1% of the systolic rise. Assuming that both our samples are fair ones, it must be concluded that under the clinical conditions obtaining *methedrine* produces a greater, and not a smaller, diastolic response than *noradrenaline*.

This may seem to labour a comparatively trivial point, but there is much that we do not know about the response of the body to pressor amines under normal and abnormal conditions, and it is therefore all the more important to keep clear what data we have, as a sound foundation for our theory and practice.—I am, etc.,

Emsworth.

P. R. BROMAGE.

Migraine

SIR,—The investigation conducted by Drs. D. A. Campbell, K. M. Hay, and E. M. Tonks (December 15, p. 1424) is of singular interest to all who have any interest in the aetiology of migraine.

The facts which have been elicited would, however, have been even more useful had the type of migraine from which each patient was suffering been made known. It is obvious to all who have any real experience of these periodic headaches, be it from an aetiological or a therapeutic standpoint, that there are various types of the disease. Some migrainous patients undoubtedly have a basic endocrine abnormality; others appear to suffer from only a form of allergic disturbance. For instance, it is difficult to imagine any glandular dysfunction which, of itself, would produce an attack of migraine twice a week; while it is equally true that a generalized desensitization with either prostigmine or, better still, histamine will, in a significant number of cases, bring about alleviation, if not cure. This occurs even though the attacks are not of the typical histamine headache type.

My own interest in migraine started when an attack was induced with an injection of oestradiol (*Lancet*, 1942, 1, 488). A similar result has been noted, though not considered worth reporting, on several occasions since. A better means of permanently relieving such type of migraine is by means of anterior pituitary lobe hormone rather than progesterone.

Yet, though water retention is perhaps the cause of headache in a number of cases, there is equally no doubt that at least 50% of patients do not note any diuresis either before, during, or after an attack. This is a question invariably put by me to all individuals examined for migraine, whose number now totals almost 800.

While migraine is a disease about which we know relatively little, there is no doubt that proper treatment will bring about great alleviation if not complete relief in about 80% of patients, whose number increases daily. There is equally no doubt that the disease must be looked upon from a broad standpoint and no one single therapy is ever likely to be the answer to the relief of so complicated a syndrome.—I am, etc.,

Putney.

NEVIL LEYTON.

Shortage of X-ray Films

SIR,—It has been common knowledge for some time that there is a serious shortage of x-ray films in this country, owing to two facts—40% export of British-manufactured x-ray films and an increased use of x-ray examinations as the result of the National Health Service.

In a recent circular letter headed "Economy in the Use of X-ray Film" (*British Medical Journal, Supplement*, December 8, p. 255), signed by the chief medical officer of the Ministry of Health, he states the increased use of x-ray films as 76% greater than in 1947 and advocates further reduction in the use of x-ray examinations. This of course is most unlikely, and instead of reduction there is likely to be a further increase.

Surely the real answer is for a long-term policy to step up production of films by increasing the factories producing these articles but as a short-term policy to reduce or entirely abolish the 40% quota of British-produced films being sent

abroad to countries such as Egypt, etc., and so permit the British public to get the maximum benefit from their Health Service.

On the Continent there appears to be no shortage of films, and recently I brought back from France a small supply. I was charged 24% duty by the Customs, and they suggested a fine of 10s. because B.E.A. officials had loaded the films in the wrong end of the aeroplane, making them arrive as luggage instead of cargo. The fine was not paid, but surely if we are to be deprived of films let us bring them back to this country without this extortionate duty and ridiculous suggestion of a fine.—I am, etc.,

London, W.1.

NORMAN P. HENDERSON.

Educating the Public About Cancer

SIR,—Dr. J. F. Brailsford's letter (November 10, 1951, p. 1154) should not be allowed to pass without comment, as it represents an attitude of defeatism towards cancer which is all too prevalent in the British Isles. It would be very difficult for Dr. Brailsford or anyone else to show that early diagnosis and treatment do not greatly improve the chances of five-year survival in a vast majority of cancers. With our present methods of treatment no one can deny that sometimes even the earliest apparent case is sometimes uncontrolled, but the chances of "cure" in the early case are very much higher than in the late case.

For the past 15 years or so there has been, in the United States and Canada, an intensive publicity campaign which has been carried out by voluntary organizations—the American Cancer Society and the Canadian Cancer Society. The result has been a very much more intelligent public appreciation of the early signs of cancer, and consequently a very much earlier diagnosis of the disease than obtains at the present time in Britain. In Saskatchewan, for instance, there has been an active Government-sponsored cancer control programme in effect since 1932 and the population has been exposed to intensive propaganda from the Canadian Cancer Society for more than 10 years. These two factors have resulted in a marked increase in the percentage of early cases of cancer seen in the Government cancer clinics in Saskatchewan (*Canad. J. publ. Hlth*, 1951, 42, 427, and *Lancet*, 1951, 2, 496).

From the years 1932 to 1944 (inclusive), 6,816 new unselected cases of cancer were admitted to the cancer clinics in this province. The crude five-year survival rate was 43% and the corrected five-year survival rate was 49%. Dr. Brailsford states he has known patients with untreated cancer live more than five years. It is undoubtedly true that occasional patients suffering from cancer do survive without treatment for this length of time. Has Dr. Brailsford, however, any statistical evidence to show that 43% of untreated cases of cancer live five years? He states that women have a nerve supply even in the breast, and cancer manifests itself to their notice before the doctor can feel it. A monograph on this very important new sign of his would be instructive to those of us who are daily confronted with women who have undiagnosed breast tumours.

Public propaganda on cancer to-day is aimed at the prevention of fear of the disease, and the incidence of so-called cancer phobia is very much lower than Dr. Brailsford seems to think. In any case, cancer phobia in itself has never proved a fatal disease. Having had some experience in cancer work, both in England and Canada, we can definitely state that there is far more fear of the disease and ignorance of its nature in England than in Canada. Man fears the unknown. What knowledge we have at present of the disease should be shared with the public, and the inevitable result will be a great increase in the number of early cases seen in tumour clinics. Dr. Brailsford's theoretical objections to public education in cancer just do not exist in practice.—We are, etc.,

Death on the Roads

SIR,—May I endorse Dr. C. W. A. Searle's remarks (December 29, 1951, p. 1583) on the laxity of both the law and the public in their attention to the necessity for good vision in driving? I frequently see myopes who either have no glasses or, if they have, do not wear them for driving. After dark, these people are particularly dangerous. I was told once by one of the latter that as he could see a number plate at 25 yards with his glasses on he felt no difficulty about signing the licence declaration though he never wore his glasses. I was once travelling in a Service vehicle which overturned because the driver's eyesight was only 6/60 when I tested her eyes a day or two later. I have also seen a patient with diplopia who was still driving.

Very often when one is driving one can tell by the attitude of a pedestrian or by his gestures that he is probably going to do something foolish. To observe these hints demands a good standard of visual acuity and saves accidents. Many pedestrians are infirm and suffer from bad eyesight themselves. If one of these unfortunates coincides in his travels with a careless myope the danger is apparent. One can hardly prohibit pedestrians with poor eyesight from crossing the roads.

It might even be advisable to treat culprits as those suspected of being drunk, so that an eyesight test is included in the routine investigation of a motorist who has been involved in a serious accident; particularly the question whether he was wearing his glasses at the time should be raised. I feel sure that a more stringent application of the law would save lives.—I am, etc.,

Greenwich, S.E.10.

P. A. GARDINER.

Trichlorethylene Analgesia in Labour

SIR,—In the article by Mr. O'Donel Browne and others (December 29, 1951, p. 1556) it is stated that it was difficult to provide analgesia for the normal delivery at home because Minnitt's apparatus was too heavy if there was poor transport; and that the use of narcotics required greater skill, experience, and supervision than they could supply.

Surely proper transport is essential for this work to be done well; and should not the skill, experience, and supervision necessary for the administration of the drugs also be considered the right of patients in their own homes? Perhaps the co-operation of general practitioners, who are accustomed to coping with the difficulties mentioned, could be enlisted. It is rather distressing to think that students and pupil midwives may be led to imagine that proper analgesia and any necessary drugs cannot be easily obtained in domiciliary practice.—I am, etc.,

Plymouth.

O. LL. LANDER.

Haemolytic Disease of the Newborn

SIR,—I read with much interest Dr. W. Walker's fine review article on haemolytic disease of the newborn (November 10, 1951, p. 1142) in the *British Medical Journal*, and would like to make the following comments.

1. The statement, "Tests for the strength of antibodies are not of much value in predicting the form or severity of the disease in the baby, and are not required," is not correct. In our own experience with tests on about 600 Rh-negative women there was a definite correlation between the maternal antibody titre and the severity of the baby's illness. In 338 Rh-negative mothers who were not sensitized the total mortality rate (stillbirths and neonatal deaths) among the babies was only 1.5%, so that non-sensitized Rh-negative mothers have as good a chance of having normal babies as Rh-positive mothers. On the other hand, among Rh-positive babies from sensitized Rh-negative women the total mortality rate was considerably higher, and was correlated with the maternal antibody titre. Thus, when the

antibody titre was four units or less by the albumin-plasma conglutination method the total mortality rate was 12.2%, while with titres ranging from 65 to 256 units the total mortality rate was as high as 72.2%. With Rh-negative babies the height of the maternal Rh antibody titre was inconsequential, because none of those babies were erythroblastic.

2. The assertion that one can predict the Rh type of the unborn baby from the Rh types of the parents requires some qualification. For example, if the husband belongs to type Rh₁Rh₁ his genotype could be either R¹R¹ or R¹r, of which the former is by far the more common and therefore the more likely. In general, therefore, one may assert with reasonable certainty that such a husband is homozygous for the Rh₀ factor, and that every child will be Rh₀ positive, and if the mother is sensitized that the expected baby will therefore be erythroblastic. One must bear in mind, however, the possibility of rare instances where the husband is actually of genotype R¹r, in which case there is a 50% chance that the baby will belong to type rh' and therefore will not be harmed by the maternal Rh₀ antibodies. A similar qualification must be made when the husband belongs to type Rh₂Rh₂, in which case his genotype could be R²r, as well as R²R². Finally, individuals of type Rh₁Rh₂ are not always homozygous for the Rh₀ factor, because they could belong to genotype R¹r or R²r as well as R¹R², to say nothing of the rarer genotypes involving genes R³ and r³.

On the other hand, individuals of phenotypes Rh₁rh and Rh₂rh are not necessarily heterozygous. For example, a person of type Rh₁rh might belong to any of the three genotypes R¹r, R¹R⁰, or R⁰r, of which the first is the most common and therefore the most likely. While most individuals of phenotype Rh₁rh are heterozygous, if a type Rh₁rh husband of a type rh woman has had two children, one type Rh₁ and the other type Rh₀, his genotype would have to be R¹R⁰, so that such a man would be homozygous for the Rh₀ factor.

Where the husband is definitely heterozygous, as proved by the previous birth of an Rh-negative baby, there is a 50-50 chance that any future baby will be either Rh positive or Rh negative. By watching the course of the antibody titre during pregnancies one may be able to predict the Rh type of such a baby. If there is a significant rise in antibody titre at any time during the pregnancy, the foetus must be Rh positive. In not one of 16 cases studied by us in which the foetus was Rh negative was there a rise in antibody titre at any time during the pregnancy or after delivery, so that reports of so-called non-specific anamnestic reactions are based on faulty technique of titration. Failure of the antibody titre to rise leaves open the question whether the baby is Rh positive or Rh negative. However, in such cases where the antibody titre had been at a high level (250 units or more) throughout the pregnancy, we have predicted correctly shortly before the birth of the baby that it would prove to be Rh negative, reasoning that were it Rh positive it should have died *in utero* by the seventh or eighth month.—I am, etc.,

Brooklyn 25, N.Y.

A. S. WIENER.

SIR,—I appreciate Dr. A. S. Wiener's interest in my article on haemolytic disease of the newborn and feel that his remarks require comment. I would remind him that the article was written for the guidance of the family doctor. Detailed consideration of the more controversial issues was therefore outside its scope. I will consider his two points in turn:

1. Throughout the past 10 years many attempts have been made to relate the antenatal maternal antibody titre to the subsequent form and severity of the disease in the infant. The results have been equivocal. In my hands, tests for the strength of maternal antibody using titrations in saline, albumin, and by the indirect Coombs test have been of little value in the individual case. I have found only a vague correlation between antibody strength and prognosis, though it may have some value in the prediction of still-

birth. This is not sufficient to influence one's conduct of the individual case, especially when one considers the multiplicity of tests required.

2. Dr. Wiener would, I think, agree that the knowledge of the father's genotype is of value (due consideration being given to the specificity of the antibody concerned). In his letter he is apparently solely concerned with the difficulty of determining this by serological tests on the father's blood. When preparing my article I decided that a discussion of these points was inappropriate. Dr. Wiener's letter leaves me unrepentant.—I am, etc.,

Newcastle-upon-Tyne.

W. WALKER.

Childhood Factors in Duodenal Ulcer

SIR,—Dr. A. Balfour Sclaire's letter (December 8, p. 1405) discloses one of the fallacious premises in Dr. Kellock's study (November 10, p. 1117). The other is that Dr. Kellock used as a control group people who were ill enough to be under the care of a hospital. The assumption is that none of them were suffering from diseases caused by emotional difficulties. Why should this assumption be made? Until a comparison has been made between people ill in hospital and people of similar age, occupation, etc., who have never been seriously ill, it is not proved that emotional conflict is not the prime cause of all disease. In such a comparison the factors influencing personality should, as Dr. Sclaire points out, include those currently regarded by psychological authorities as being most important in producing emotional conflict in some individuals. Clearly such a piece of work would entail the spending of much time and patience, but the results might give the protagonists of "psychosomatic" medicine some very sure ground to stand on.—I am, etc.,

London, E.1.

ALAN WATSON.

Gastric Carcinoma and Acute Perforation

SIR,—The risk of malignancy in perforated gastric ulcer has, of course, been known for some time. Of a personal series of 44 perforations six were gastric in type. In view of the known risk, once again stressed by Mr. Terence L. Kennedy (December 22, 1951, p. 1489), wherever possible excision of the ulcer was carried out and repair of the stomach performed. This had two advantages: the induration and oedema sometimes found may make suturing difficult and closure uncertain—the clean-cut edges of the operation excision can be sewn together with ease, making repair simple. Complications such as fistula formation, which occasionally occur, are thus avoided. The second advantage is that the whole ulcer area can be sent for section and the diagnosis of malignancy made with certainty and speed. There has been no difficulty when this procedure has been carried out. In Mr. Kennedy's series this manoeuvre was not possible in all cases, since a number of these had obvious tumours, but it should be kept in mind and employed more often.

Finally, gastric carcinoma may occur with an independent gastric ulcer and a case of simultaneous perforation must be unusual. Without going into clinical details, which were not exceptional and presented a typical picture—a carcinoma of the pylorus was found to be perforated, and on the body of the stomach, quite separate, was a clear-cut independent ulcer which had also perforated.—I am, etc.,

Stourbridge.

MAURICE HERSHMAN.

"Robaden" and Enterogastrone

SIR,—The note on "New Treatments of Peptic Ulcer" contained in "Any Questions?" (October 6, 1951, p. 862) has come to my attention. The attitude of caution taken by the commentator is most commendable, but certain mis-statements require correction. The Swiss preparation "robaden" is compared with the enterogastrone preparations of the American workers as though both were only different brand names of a common preparation. Actually

what has come to be known as "enterogastrone" is an extract of the mucosa of the upper small intestine: it would appear to be of a protein nature: its chief pharmacological action is inhibition of gastric secretion. Robaden, on the other hand, is a protein-free extract of the total stomach and small intestine and does not have the pharmacological action of enterogastrone in depressing gastric secretion. Without exception the papers published in America have dealt with enterogastrone only, and it is therefore obvious that conclusions drawn from the American studies cannot be applied to robaden.

Among the European papers you cite you have stressed one which gives attention to the importance of psychological influence of the doctor on the ulcer patient. Although psychological factors in the therapy of ulcer disease play an important part—as they do also in other chronic diseases such as arterial hypertension, rheumatic processes, etc.—sustained success in therapy cannot be achieved by the administration of placebo preparations.

May I draw your attention to the fact that in 1944 I was the first to report on good results with robaden in ulcer therapy? In 1951 I published a second paper on our findings since 1944, and could report confirmation of the earlier good results obtained by me and my colleagues.—I am, etc.,

Solothurn, Switzerland.

H. SCHMASSMANN.

Technique of Shock Therapy

SIR,—It is my experience that both "tubarine" and "flaxedil" can produce a sense of suffocation in the conscious patient even when administered in smaller doses than those mentioned by Dr. D. T. Maclay (December 15, 1951, p. 1464) and that it is the apprehensive or uncooperative patient who is most likely to show distress. Dr. Maclay finds his technique to be satisfactory for a special type of case, but in principle it seems undesirable to allow these drugs to develop their effects without the cover of some form of narcosis. I believe that there are very few patients to whom a sleep dose of thiopentone may not be administered with safety, provided that they are given oxygen to breathe—preferably beforehand—and are kept well oxygenated up to a moment of stress.—I am, etc.,

Huyton, near Liverpool.

J. R. ESPLEN.

Antihistaminics in Rheumatoid Arthritis

SIR,—I was interested to read in Professor Edward C. Kendall's Heberden Oration (December 1, 1951, p. 1295) that he seems to favour the view that rheumatoid arthritis may be due to a hypersensitivity state. If the disease were the result of the combination of an antigen (i.e., a foreign protein) and an antibody, cortisone could act either by modifying the rate of production of the antigen or by protecting the tissue from the effects of the products of such a combination. Presumably histamine, or a histamine-like substance, is likely to be involved.

So far as I know antihistamine drugs have no effect on cases of established rheumatoid arthritis, but the following case may be of interest in this connexion.

A middle-aged woman had been subject to fleeting attacks of pain and swelling in various joints for just over a year. The attacks came on suddenly and affected chiefly wrists, elbows, knees, and ankles. The pain and swelling generally subsided in a day or two, and there was no residual disability.

The attacks had been becoming more frequent and severe in the two months prior to her attendance at the clinic, and she was developing minimal swelling with stiffness of the proximal interphalangeal joints of the fingers. I diagnosed "palindromic rheumatism," which, in my experience, is generally an unusually prolonged period of prodromal symptoms heralding the onset of true rheumatoid arthritis.

However, in view of the fact that some authorities regard palindromic rheumatism as a separate entity due to an allergic state, I suggested to the patient's doctor that it might be worth while trying the effect of "anthisan" (one tablet thrice daily). This drug produced a dramatic relief of symptoms. The patient has not had any pain or swelling in any joints for over three months, and the swelling in the interphalangeal joints has subsided.

I have tried the effect of this drug on several similar cases in the past and it produced some symptomatic relief in all. I am aware that these observations are not in any way conclusive, but it would be of great interest to learn what success other practitioners have had in treating rheumatic diseases with antihistamine drugs.

In view of the absence of any direct proof that rheumatoid arthritis can be attributed to a hypersensitivity state any indirect evidence to support such a theory is of special importance.—I am, etc.,

Watford.

RICHARD W. BARTER.

POINTS FROM LETTERS

"Primary Atypical Pneumonia"

Major D. HAMILTON (B.A.O.R. 16) writes: A lot of "atypical pneumonia" I have seen bore little resemblance to the disease described by Dr. D. M. Baker (November 24, p. 1277). It was very easily diagnosed. It must be remembered that Coxsackie viruses, *Rickettsia burneti*, and the influenza viruses are all occasionally indisputable causes of the typical pneumonitis. The most promising approach to the subject is through the laboratory. The picture of benign pneumonitis varies greatly with place and time both in course and cause. As I saw it in Cyrenaica it was probably aspiration pneumonia, for it strongly favoured the dependent segments and subsegments, especially the axillary subsegments and the apical segment of the lower lobe. As originally described by a U.S.A.M.C. major it was thought to be influenza. . . . We are shaking the mantle of the Oslerian tradition off. Just as well. The reconciliation of the divorced parties of diagnosis and treatment under the one approach of management of the case, and the recall of treatment from the wilderness, was essential. The Oslerian tradition, with its overemphasis on passive observation rather than management, did not even result in a complete catalogue of the common diseases. This is not to criticize the efforts of these physicians. Their approach was necessary. It has served its purpose.

Registered Drug Samples

MENLEY & JAMES write: We have received reports of annoyance caused to doctors by the early delivery of registered packets containing samples (see *Journal*, November 24, 1951, p. 1285). A number of drugs and preparations which are controlled by the Poisons legislation may only be supplied against the signed order of a registered medical practitioner, and when supplied through the post they must be sent by registered post. We have followed this procedure for a number of years, but it seems that, paradoxically, because of improvement in the postal delivery services it is now giving rise to annoyance. We have taken up the matter of delivery with the Post Office, and in consultation with them we are arranging to incorporate on registered packages sent in response to requests for samples the following wording: "Postmaster—not first delivery, please." We can only make this request, but we understand that if a doctor complains to his local post office that he is being disturbed at an early hour by the arrival of packages the local office would arrange for packages to arrive during a later delivery.

Incontinence in a Woman

Dr. S. BRENNAN (Nottingham) writes: It is easy enough to enumerate the causes of incontinence in a man, but what of incontinence in a woman? Recently I received a 'phone message from a woman who appeared by her tone to be in great anxiety. When I arrived she told me that her urine was constantly dribbling. She gave me a history of this going on for a few weeks, but only after micturition, and she had paid little attention to it; but one day it became continuous—and thus her urgent 'phone call. I visualized a fibroid or a growth or some displacement. Abdominal examination revealed nothing. When I proceeded to do a P.V. I found complete atresia of the vulva, which was completely shut off by a thin membranous tissue. There was just a pin-point opening, surrounded by a red areola. Next day I examined her under an anaesthetic and broke down and stretched the membrane. She has been perfectly well ever since. She is a woman of 62 years, strong, healthy, and not of the neurotic or hysterical type. At the age of 31 she gave birth to a 9½ lb. (4.1 kg.) baby, this being the only child. It was a normal delivery, but she was badly torn and required several stitches. Here was the extraordinary case of a woman urinating into the vagina and thence through this tiny opening, giving rise to the incontinence. I should like to know if this is an unprecedented case. I have never seen anything like it in my 30 years of practice.

Obituary

Dr. G. L. THORNTON, who died on December 4, 1951, at the age of 79, will be remembered with affection by a wide circle of ex-Service men and women, members of the Regular Armed Forces and the Territorial Army whose services extend over the two world wars. George Lestock Thornton was educated at Rossall School, Trinity College, Cambridge, and St. George's Hospital. He qualified in 1897, and after a period of general practice at Holt, Norfolk, and Ilfracombe, North Devon, he returned to St. George's Hospital as casualty officer and medical registrar before setting up again in general practice in Exmouth, South Devon, in 1903, in which year he obtained the M.R.C.P. He was a keen and shrewd clinician who strove always to keep abreast of expanding medical knowledge, and at the same time never losing the human and kindly touch of the family doctor. For many years he was secretary of the Devon and Exeter Medico-Chirurgical Society and medical officer to the Exmouth Cottage Hospital. In addition to the duties of a busy professional life he did not shirk civic responsibility and served on his local district council (whose chairman he was at the outbreak of the first world war, and again in 1919) and later on the Devon County Council. In 1915 he volunteered for service with the Royal Army Medical Corps and served first in Malta and later in France, Salonika, and Palestine with the 2/6 London Field Ambulance. He was awarded the M.C. and bar while acting as regimental medical officer to the 303 Brigade, R.F.A. After returning to general practice in 1919 for a short period he accepted full-time employment with the Ministry of Pensions Medical Services, becoming Deputy Commissioner of Medical Services, Exeter, which post he held until his retirement under the age limit in 1937. In recognition of his service he was appointed C.B.E. At the outbreak of the second world war he was recalled to temporary duty and served as Commissioner of Medical Services, South-west Region, until the conclusion of hostilities. Between the two wars he devoted much time to the Territorial Army, commanding the 128 Wessex Field Ambulance and later becoming A.D.M.S. of 43 (Wessex) Division and honorary colonel, 43 Division Medical Services. He held the post of Honorary Physician to King George V from 1930 to 1934. Always keenly interested in the welfare of ex-Service men and women, he was a member of the British Legion and took office as president of his local branch on his final retirement from the Ministry of Pensions. He married Letitia Anna Cordner in 1898. During the second world war he suffered the tragic loss of his wife, who was killed in a daylight air-raid on Exmouth in 1943, when his house was totally destroyed. He is survived by his three sons, two of whom are members of the medical profession, and one daughter.

Dr. NESTOR JOHN STANLEY NATHAN died on December 13 after a short illness at the early age of 41. He was a student at Charing Cross Hospital and qualified in 1932. After appointments as house-physician and house-surgeon, at his own hospital, and as house-physician at the London Chest Hospital, he began his career in public health as an assistant medical officer at the Surrey County Council's Sanatorium at Milford. He then moved to the West Riding of Yorkshire, where he remained 13 years, first as assistant county medical officer of health and subsequently as medical superintendent first of the General Hospital at Wakefield and then of the Staincliffe Hospital, Dewsbury. It is particularly as holder of these two last appointments that he will be remembered in the West Riding with gratitude and affection, since it was due in no small measure to his enthusiasm and inspiration that these two hospitals were entirely transformed from backward institutions into the modern and fully equipped general hospitals they are to-day. In 1943 Dr. Nathan took the D.P.H. and in 1946 the D.R.C.O.G. In 1950 he returned

THE CHEMOTHERAPY OF TUBERCULOSIS WITH P.A.S.

'PASHETS'THE SHORT NAME FOR
'PARAMISAN' CACHETS**mean efficiency for
the busy staff**

'Paramisan' Cachets are simple to handle from dispensary to patient. They provide an accurate dose without weighing or measuring. They do not decompose on storage or spill in use. There is no waste.

Consider these further advantages —

- **ABSOLUTE FRESHNESS** 'PASHETS' bring the drug fresh to the patient.
- **CERTAIN LIBERATION** 'PASHETS' disintegrate quickly when swallowed, thus ensuring rapid and certain liberation of the drug.
- **ACCEPTABLE TO PATIENT** 'PASHETS' are surprisingly easy to swallow, leave no unpleasant taste and mean less "swallows", per day. These advantages maintain the co-operation of the patient — make for quicker recovery and rehabilitation.
- **IDEAL FOR DOMICILIARY TREATMENT** 'PASHETS' are easy to dispense, convenient to carry, accurate and simple to take.

Without doubt, an efficient and acceptable form of presentation for the patient and the staff. The truly economical way to buy and administer P.A.S.

VIMALTOL

A Delicious Concentrated Vitamin Food

TO the physician requiring a product which incorporates important vitamins in a form acceptable to every patient, 'Vimaltol' presents special advantages.

'Vimaltol' is made from specially prepared malt extract of high protein content, yeast—one of the richest sources of vitamin B—and Halibut Liver Oil, an important source of vitamins A and D. It is also fortified with additional vitamins and mineral salts, and is deliciously flavoured with orange juice.

'Vimaltol' is thus an important aid in the

treatment of the many abnormal conditions resulting from the deficiency of one or more of the essential vitamins in the average everyday dietary.

The routine use of 'Vimaltol' helps normal development of the growing organism and the maintenance of correct metabolism, while raising the general resistance against infection.

'Vimaltol' has thus a very wide application in general practice for patients of all ages. It can be prescribed with advantage at all seasons.

For menopausal disorders, pre-menstrual tension and dysmenorrhœa

THE ASSOCIATION of methyl-testosterone with ethinyl œstradiol in Mepilin permits a marked reduction to be made in the effective dosage of œstrogen for the control of menopausal symptoms. Advantages of Mepilin are:—

1. Production of an increased sense of well-being
2. Avoidance of undesirable side effects such as breast turgidity and pelvic congestion
3. Reduced risk of inducing uterine hæmorrhage or withdrawal bleeding

'MEPILIN'

Tablets containing ethinyl œstradiol 0.01 mg., and methyl-testosterone 3 mg. Bottles of 25 and 100 tablets.

MEP/R/2

to public health as area medical officer for the Staffordshire County Council, but unfortunately his untimely death has cut short the excellent work he was doing in that sphere. He leaves a widow and two young sons, to whom the sympathy of his friends and colleagues will be extended.

Dr. ANDREW BROWNLIE died on December 13, 1951, at his home in Hamilton at the age of 75. He graduated M.B., Ch.B. at Glasgow University in 1899, and after two years' service as an assistant medical officer in Brislington Hospital, near Bristol, he became assistant in 1902, and partner in 1904, of the late Dr. James Adam, of Hamilton. When Dr. Adam gave up general practice to specialize in throat and nose work, Dr. Brownlie carried on the practice on his own until January, 1951, when ill-health caused his retirement. He had celebrated his jubilee in medicine 18 months before. During the first world war he served for two years in the R.A.M.C., mainly in Egypt and Malta. A regular churchgoer, he was an elder for many years. Though of quiet and reserved disposition, he was popular with his colleagues and patients. In 1932 he served for a year as chairman of the Lanarkshire Division of the B.M.A. He was a keen bowls player, and won prizes over many years. His wife predeceased him in 1942.

Dr. WILLIAM HOLBERTON SQUARE died at his home in Leighton Buzzard on December 18 at the age of 91. He had been in practice in the town since 1898. A member of a well-known Devon family, he was born at Kingsbridge, South Devon, and educated at Sherborne School and St. Bartholomew's Hospital. When he was a student he dissected with D'Arcy Power, and he delighted to tell stories of Matthews Duncan and Tom Smith. After qualification in 1884 he went into practice at Newton-le-Willows, in Suffolk, and from there he went to Sunderland, where his busy general practice included over 150 "midder" cases a year. Anxiety about his wife's health caused a move south, and he came with three young children to Leighton Buzzard just before the end of the century. Life was leisurely. There were no regular surgeries, and hunting with the stag-hounds in winter provided relaxation. Visiting in those days was done on horseback by day and a bicycle at night. Then a smart American "buggy" provided more comfortable transport, and in 1907 a baby Peugeot was obtained, succeeded from time to time by more roomy and reliable cars. Hunting continued to be his favourite relaxation until at 73 he had a fall and injured his shoulder. Even after that a horse was favoured for a few afternoon visits after the bulk of the work had been done by car in the morning. He was medical officer of health to the Eaton Bray Rural District Council until it merged into Luton Rural District Council, and to the Wing Rural District Council for 27 years, until after his 90th birthday. He was an active Freemason and was made a Grand Deacon of England in 1937. To successive generations in his practice he became an institution. He had never been ill—three days at the outside with mild influenza was all he could remember—and to many of his patients it seemed impossible that a time would come when he could no longer pay his usual visits. But 10 days before his death he felt too tired to carry on, and the end came just three weeks after his 91st birthday.—A. O. B.

Dr. WILLIAM ALFRED CARDEN died suddenly on December 27, 1951, in Johannesburg at the age of 79 years. He studied medicine at Guy's Hospital, qualifying in 1895. Four years later he went to Korea, where he worked as a medical missionary with the English Church Mission. In 1903 he settled in South Africa and began to practise at Fraserburg. Some years later he moved to Bothaville, in the Orange Free State, where he was in practice for 22 years: for a time he was district surgeon there. In 1930 he moved again, this time to Worcester, in Cape Province, and he continued in practice there until his retirement in 1942. He then settled at Deneyville, where he lived until the time of his death. His passing will be mourned by many of his colleagues in South Africa.

Medico-Legal

RESTRICTIVE COVENANT APPEAL DISMISSED

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

On December 13, 1951,¹ the Court of Appeal dismissed the appeal of a doctor against the decision of Mr. Justice Danckwerts, previously reported in these columns,² upholding a restrictive covenant in the partnership deed of the partnership from which the doctor had recently retired and granting an injunction forbidding him to practise as a general medical practitioner within a radius of 10 miles from Atherstone Parish Church.

In his judgment the Master of the Rolls said that, although the evidence showed that only 1% of the patients of the practice lived outside a radius of five miles, that 1% included the more affluent private patients who had cars to take them to the principal surgery, and accounted for more than a third of the total income. He found nothing vicious in the 21-year time restriction in the covenant, because, although this might amount to life banishment from the area, a doctor was a relatively mobile person and the whole of the United Kingdom was open to him. Nor did he find anything unreasonably wide in the covenant's formula "directly or indirectly carrying on or being interested or concerned in carrying on the business or profession . . ." Such a formula used in connexion with professional men did not carry the covenant beyond what was reasonably required to protect the continuing and remaining partners against competition. Accordingly, if radius, length of time, and the width of language used were taken, the total result of the covenant did not produce anything unreasonably wide.

His Lordship then went on to consider the effect on the matter of the National Health Service Act, 1946, and the Amending Act of 1949. While the plain intention and effect of Section 35 of the 1946 Act was to prevent doctors who practised, as these doctors did, in the Service from selling the goodwill of their practices, the section did not have the effect either of destroying the goodwill or of vesting it in the State or any emanation of the State. Goodwill remained one of the assets of the firm, on the creation and preservation of which the livelihood of the partners continued substantially to depend. This view of the matter was implicit in Section 1 (5) and (12) of the Amending Act of 1949, which showed that the element of goodwill was not so taken away that the ordinary principles otherwise applying to this restrictive covenant no longer did so. Nothing in the new legislation therefore invalidated this covenant, which was a valid covenant when made in 1945.

Lord Justice Birkett and Mr. Justice Upjohn concurred in dismissing the appeal and affirming the order of Mr. Justice Danckwerts, and the enforcement of the injunction was suspended until December 31, 1951.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC, TRINITY COLLEGE

The following medical degrees were conferred on December 6:

M.D.—T. T. Chapman, E. R. N. Cooke.

M.Ch.—J. E. F. Coolican.

M.A.O.—A. D. H. Browne.

M.B., B.Ch., B.A.O.—N. Boland, Norma E. Boyd, Iris E. Byers, E. D. Cooke, D. L. Cowan, Patricia G. Ellis, Phyllis E. Featherstone (formerly McCready), K. W. M. Harbord, W. Jackson, Ethel G. Jennings, T. D. Kimmert, R. King, G. J. Malseed, Edith P. Pringle, Aileen F. Smith, W. McC. Wilson, B. W. Withrington.

UNIVERSITY OF LONDON

The following candidates have been approved at the examinations indicated:

M.S.—*Branch I (Surgery)*: A. G. Ellerker, B. W. Wells. *Branch IV (Otolaryngology, Rhinology, and Laryngology)*: J. A. Harpman.

UNIVERSITY OF SHEFFIELD

At a Degree Congregation held on December 18, 1951, degrees in the Faculty of Medicine were conferred as follows:

M.D.—G. M. King.

M.B., Ch.B.—A. H. Askew, Phyllis B. Banks, Hilda M. Brunt, D. A. Ewing, M. Falconer, G. Flowers, Phyllis B. Hobbs, J. K. Johnson, J. H. Nicholls, D. L. Price, Mrs. Zoe C. Randall, Olga R. Raphael, D. Waddington.

QUEEN'S UNIVERSITY, BELFAST

At a Graduation Ceremony held on December 19, 1951, the following medical degrees were conferred:

M.D.—¹R. F. Whelan, ²Wilmert F. I. Brown, ³W. F. McAuley, W. Bingham, W. B. S. Crawford, J. K. A. Dorman, S. Kay, K. L. Stuart, A. P. Trimble, D. G. C. Whyte.

M.Ch.—H. C. Dales.

M.B., B.Ch., B.A.O.—Adela M. Blair, Sarah F. Charlton, D. McL. F. Drew, L. Fenton, J. L. Houston, T. J. McCabe, G. A. McCann, J. J. McCavana, I. A. McQuade, H. G. S. Murray.

¹With high commendation. ²With commendation.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on December 19, 1951, with Professor Walter Mercer, President, in the chair, the following candidates who had passed the requisite examinations were admitted Fellows: T. L. Barclay, F. Bauer, Lydia Colaco, J. K. Craig, H. A. F. Dudley, A. S. Lambert, D. G. Lane, F. D. Martinson, S. Mishra, A. H. McCallum, J. A. McCredie, I. G. Mackenzie, S. Nand, W. H. Rutherford, L. Stein, D. P. Viljoen, J. A. S. Wilson.

Professor Robert Humphrey McKeag, M.B., B.Ch., B.Dent.Sc., of the Department of Dental Surgery, University of Ceylon, was elected a Fellow in Dental Surgery without examination.

The Services

A Supplement to the *London Gazette* has announced the following awards:

First, Second, and Third Clasps to the Territorial Efficiency Decoration.—Major H. R. Paterson, T.D., R.A.M.C.

First Clasp to the Territorial Efficiency Decoration.—Lieutenant-Colonel D. W. E. Lloyd, M.C., T.D., and Major H. Dickie, T.D., R.A.M.C.

Territorial Efficiency Decoration and First Clasp.—Majors G. W. Monro and J. R. S. Third, Captain J. P. Collinson, R.A.M.C.

Territorial Efficiency Decoration.—Lieutenant-Colonel E. F. Hill, Captain (Honorary Major) G. G. Cochrane, and Captain J. L. Carmichael, R.A.M.C.

CASUALTIES IN THE MEDICAL SERVICES

Prisoners of War.—Captains R. P. Hickey and D. R. Patchett, R.A.M.C., attached R.U.R.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending December 22 (No. 51) and corresponding week 1950.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 126 great towns in England and Wales (London included), London administrative county, the 16 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 13 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

Vital Statistics

London's Health in 1951

According to a preliminary report issued by Sir Allen Daley, London County Medical Officer of Health, the provisional birth rate in London for 1951 was 15.8 per thousand population. It has declined progressively from the peak of 1947, when it was 20.9. The average for the decade 1931-40 was 13.8. The provisional death rate was 12.7 per thousand, which is slightly higher than the rate for any of the years 1946-50 but the same as the rate for the decade 1931-40. This slight rise in mortality may be partly attributed to the influenza epidemic earlier in the year.

The provisional infant mortality rate was 26 per thousand live births. This was the same as the rate in 1950 and lower than any previously recorded rate. For 1931-40 the rate was 60. The provisional neonatal mortality rate (i.e., of children under four weeks) was 17.4 per thousand live births, as compared with 24 for 1931-40.

The provisional death rate for tuberculosis was 0.38 per thousand—a new low record, and 0.02 below the rate for 1950. Notifications of new cases fell slightly from 5,718 in 1950 to 5,476. Fatal road accidents increased in number; there were 303 deaths (provisional figure) as compared with 245 in 1950. There were 44 deaths from infantile diarrhoea, which is a record low figure.

Week Ending December 29

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,095, whooping-cough 1,402, diphtheria 43, measles 2,331, acute pneumonia 678, acute poliomyelitis 20, dysentery 293, paratyphoid fever 7, and typhoid fever 3.

Infectious Diseases

In England and Wales during the week ending December 22, 1951, notifications of whooping-cough decreased by 110 and measles by 127, while notifications of acute pneumonia decreased by 98 and dysentery by 85.

The decline in the incidence of whooping-cough was mainly contributed by the midland counties. The largest fluctuation was a rise of 47 in Yorkshire West Riding. Small fluctuations occurred in the local trends of scarlet fever, and the total for the country was only 9 more than in the preceding week. For the second consecutive week a rise of 12 in the number of notifications of diphtheria was recorded, and the total was the largest for over a year. The largest variations in the local trends of diphtheria were a rise of 8 in Staffordshire and a fall of 4 in Cheshire. The largest increases in the incidence of measles were Cardiganshire 71 and Kent 44, and the largest decreases were Staffordshire 61 and Durham 49.

In Suffolk 14 further cases of paratyphoid fever were notified; 10 cases were reported in this county in the preceding week. The largest centres of infection during the week were Stowmarket U.D. 8 and Hartismere R.D. 5.

The notifications of acute poliomyelitis were 14 fewer for paralytic and 2 fewer for non-paralytic cases than in the preceding week. The largest returns during the week were those of Kent and Cambridge with 3 cases each.

A further 93 cases of dysentery were notified during the week from the outbreak in Norwich C.B. The other large centres of infection were Middlesex 65 (Staines U.D. 13, Willesden M.B. 12); Northumberland 39 (Rothbury R.D. 37); Southampton county 31 (Portsmouth C.B. 15, Havant and Waterloo U.D. 10); London 29; Lancashire 29; Durham 17 (Jarrow M.B. 11); Essex 15; Leicestershire 12 (Leicester C.B. 12); and Yorkshire West Riding 12.

In Scotland the number of notifications of dysentery was 109 more than in the preceding week because of an outbreak in Lanark county with 101 notifications. The other large return from Scotland was 27 for Glasgow.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1942-50 are shown thus -----, the figures for 1951 thus ————. Except for the curves showing notifications in 1951, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Health in Singapore

A notable feature of the population on Singapore Island is its great increase in the last 30 years. From just over 400,000 in 1921 it has grown to just over a million in 1950 (*Annual Report of the Medical Department of the Colony of Singapore, 1950*). From 1911 to 1931 the increase was some 83%, and the cause was mainly immigration from India and China. Since 1931 the population has grown by about 82%, mainly because of the steady increase of births over deaths. While in 1931 there were 584 females to 1,000 males, there are now 855, a factor of much significance to the recent population increase.

The infant mortality rate in 1950 rose to 82 from the 1949 low record of 72. These figures may be compared with pre-war returns of 130 in 1939 and 191 in 1931; the rate in 1944 was 285. The present rate is similar to that for England and Wales in 1920. The maternal mortality rate continued to decline and was 1.85 per 1,000 total births as compared with 4.0 in 1939.

The following were the death rates per million in 1950 from certain causes (with the corresponding figures for 1939-41 in parentheses): pulmonary tuberculosis, 1,193 (2,288); malaria and unspecified fever, 806 (1,547); beriberi, 242 (873); violence, 486 (637); heart diseases, 558 (655).

Medical News

Lady Tata Memorial Trust

The Trustees of the Lady Tata Memorial Fund invite applications for grants, scholarships, or fellowships for research on diseases of the blood, with special reference to leukaemia, in the academic year beginning October 1, 1952. They are open to workers of any nationality, in any country in which payment is possible. Grants are made for research expenses or to provide scientific or technical assistants for senior workers. Scholarships are awarded for the personal support of those carrying out approved research under suitable direction; their normal value will be £600 for whole-time work, with a proportional adjustment for work on a part-time basis. In addition the Trustees may award one or more Lady Tata Memorial Research Fellowships to workers with considerable research experience; the stipend of these fellowships is £1,000 per annum. Further particulars and forms of application may be obtained by writing to the secretary of the Scientific Advisory Committee, c/o Medical Research Council, 38, Old Queen Street, Westminster, London, S.W.1. Applications must be submitted before March 31, and the awards will be announced by the Trustees in June.

Emergency Bed Service: Applications and Admissions

During the seven days ending January 7 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,294, of whom 85.23% were admitted.

Formation of a Persian Gulf Medical Society

A medical congress was held in Bahrain Island in the Persian Gulf on November 14 and 15 last. The meeting was arranged by the Bahrain Medical Society, which had invited medical organizations in the area to send representatives. Forty-five doctors attended, of whom 27 were visitors from other parts of the Persian Gulf area and beyond. Among those present were representatives of the medical departments of local governments, oil companies, and American missions, as well as medical officers from the Royal Navy and Royal Air Force. They included American, Arabian, British, Indian, Lebanese, Pakistan, and Palestinian nationalities. The congress was opened in person by the Ruler of Bahrain. The meeting was mainly clinical, and included

"Midwifery among the Arabs," by Dr. Isabel Doeg (Bahrain), "Intramedullary Nailing of Fractures," by Dr. Harold Lohnaas (Arabia), "Treatment of Juvenile Tuberculosis with Streptomycin," by Dr. Naif Hassan (Kuwait), and "National Health Service," by Dr. C. A. Bozman (Cairo). Films lent by the British Council were shown. A proposal to found a Persian Gulf Medical Society open to all bona-fide medical practitioners in the area was adopted with enthusiasm, and the second afternoon of the meeting was devoted to a discussion on its formation and constitution. In the absence of Dr. R. Biggar (Bahrain), from whom the proposal originated, Dr. W. J. Moody (Bahrain) outlined the proposed aims and scope of the society, which were (i) to bring into professional and social contact all recognized medical practitioners in the Persian Gulf area irrespective of creed or nationality, (ii) to hold an annual clinical meeting at which medical problems common to the area would be discussed, and (iii) to organize investigations in certain fields (e.g., tuberculosis, venereal disease, trachoma) of particular local interest or importance. Visitors, many of whom were accompanied by their wives, were given hospitality by the Bahrain Government, the Bahrain Petroleum Company, and various private individuals. Members of the congress and their ladies attended a dinner given by the Ruler, and were also entertained by the Political Resident and by the General Manager of the Bahrain Petroleum Company. It is hoped that the first of the annual meetings of the Persian Gulf Medical Society as such will be held in Kuwait towards the end of 1952.

Publications Received

South-east and the South-west Metropolitan Hospital Regions Maps.

British Journal of Psychiatric Social Work. No. 5: Association of Psychiatric Social Workers, price 5s.

M.B.E. Awarded to Laboratory Technician

Among the New Year Honours was an M.B.E. for Mr. L. W. Collison, technical officer at the National Institute for Medical Research, who is known and respected by physiologists and pharmacologists all over the world for his work as senior technical assistant in the physiological laboratories there. He started his career as a boy of 14 in the Burroughs Wellcome laboratory under Sir Henry Dale and accompanied him to the National Institute in 1920. He has designed and built apparatus for many distinguished scientists. His award is not only a recognition of his personal qualities but a sign of increasing awareness of the importance of the laboratory technician in medical research.

Australasian Annals of Medicine

The Royal Australasian College of Physicians is to publish a new journal, *Australasian Annals of Medicine*. This journal is intended for original observations and investigations. It will appear twice a year, commencing in May, 1952, and will replace the *Proceedings of the Royal Australasian College of Physicians*.

Dangerous Drugs Act, 1951

This new Act came into force on January 1, and consolidates all existing legislation in this field without introducing any novelties. It is therefore now the sole legal reference.

Wills

Mrs. Evelyn Imelda Chichester Tudor-Edwards, widow of Mr. A. Tudor-Edwards, left £92,014. She left £5,000 to the President and Council of the Royal College of Surgeons of England, to found a Fellowship for the advancement of and research into surgical science.

COMING EVENTS

Oxford Medical Club Dinner

The Oxford Graduates Medical Club dinner is to be held at the Royal College of Surgeons on February 8. Tickets (30s.) can be obtained from the honorary secretary, 73, Harley Street, London, W.1.

Religion and Evolution

A conference on religion and evolution will be held at University College, London, on March 7 and 8. Ample time will be allowed for discussion of the interrelations between religion and evolution, and particularly of the practical problems encountered by teachers in the classroom. The fee for the whole conference is 7s. 6d., and for single sessions 2s. 6d. Tickets may be obtained from the Secretary, British Social Biology Council, Tavistock House South, Tavistock Square, London, W.C.1.

First European Congress of Cardiology

A European congress of cardiology will be held in London in September, 1952, organized by the British Cardiac Society, which has appointed Sir John Parkinson to act as chairman of the congress, in collaboration with the presidents of the European Society of Cardiology. The congress will be open to all members of European national cardiac societies affiliated to the European Society of Cardiology, and will be limited to them. Non-members may attend the scientific sessions by invitation of the organizing committee. The congress will be held at the University of London, Bloomsbury, W.C. The Chancellor's Hall at the University will open at 10 a.m. on Tuesday, September 9, for registration and for distribution of papers, tickets, and information. The scientific sessions will be held on September 10, 11, and 12 in the Beveridge Hall and the Deller Hall in the University building. Forms of application for membership will be sent out soon and further details of the programme will be announced. All correspondence relating to the congress should be addressed to Dr. K. Shirley Smith, Organizing Secretary, the European Congress of Cardiology, the Institute of Cardiology, 35, Wimpole Street, London, W.1.

International Diabetes Federation Congress

A congress on diabetes mellitus will be held at Leyden, Netherlands, from July 7 to 12, 1952. Further details may be obtained from Dr. F. Gerritzen, 33, Prinsegracht, The Hague, Netherlands.

International Society of Haematology

The fourth international congress will be held in Mar del Plata, Argentina, September 21 to 26. Subjects to be discussed include the aetiology and treatment of leukaemias, polycythaemia of altitude, haemolytic disease in newborn infants, etc. The registration fee has been fixed at \$100 (Argentine currency), and all information may be obtained from the secretaries-general, Dr. Marcel Bessis, 53, Boul. Diderot, Paris, 12e, and Dr. Sol Haberman, 3301, Junius Street, Dallas, Texas, U.S.A.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Friday

- INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 11, 5.30 p.m., "Surgery of the Heart: General Survey," by Dr. Maurice Campbell.
- WEST KENT MEDICO-CHIRURGICAL SOCIETY.—At the Miller Hospital, Greenwich High Road, London, S.E., January 11, 8.30 p.m., The Purvis Oration by Sir Heneage Ogilvie.

Monday

- HUNTERIAN SOCIETY.—At Mansion House, London, E.C., January 14, 8.30 p.m., "Endocarditis," Hunterian Lecture by Professor W. Löffler (Zurich).
- INSTITUTE OF PSYCHIATRY, Maudsley Hospital, Denmark Hill, London, S.E.—January 14, 5.30 p.m., lecture-demonstration for postgraduates by Dr. E. Stengel.
- MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—January 14, 8.30 p.m., "Radioactive Isotopes," discussion to be introduced by Professor E. J. Wayne and Mr. H. Miller.
- ROYAL EYE HOSPITAL, St. George's Circus, Southwark, London, S.E.—January 14, 5 p.m., "Non-paralytic Strabismus. The Care and Treatment of the Squinting Child," by Dr. T. H. Whittington.

Tuesday

- BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 15, 5.30 p.m., "The Philosophy of Science," by Professor H. Dingle, D.Sc.
- CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 41, Queensgate Terrace, London, S.W., January 15, 8.30 p.m., fourth ordinary meeting of 55th session. "Mount Everest," discussion to be opened by Dr. Raymond Greene. Illustrated with lantern slides.
- INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 15, 5.30 p.m., "Skin Manifestations of Malignant Diseases," by Dr. L. Forman.
- ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—January 15, 5 p.m., "Some Concepts of Rheumatic Disease," Goulstonian Lecture by Dr. J. H. Kellgren. (See also January 17.)

Wednesday

- BIRMINGHAM MEDICAL INSTITUTE, 154, Great Charles Street, Birmingham.—January 16, 8 p.m., inaugural meeting of new Section of Psychiatry of Birmingham Medical Institute.
- INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 16, 5.30 p.m., "Mycology—Actinomycosis and Nocardiosis," by Dr. R. W. Riddell.
- INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., January 16, 4.30 for 5 p.m., "Retention of Urine in Childhood," by Mr. D. I. Williams.
- ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St. Vincent Street, Glasgow.—January 16, 5 p.m., "Mistomers in Tumour Nomenclature," Finlayson Memorial Lecture by Professor R. A. Willis.
- ROYAL MICROSCOPICAL SOCIETY, Tavistock House South, Tavistock Square, London, W.C.—January 16, 5.30 p.m., annual general meeting. Film demonstration: "Motility and Flagella," by Professor A. Pijper; "Instrumental Insemination of Bees," by Mr. C. P. Abbott, in collaboration with Rothamsted Experimental Station; "Life Cycle of the Malaria Parasite," by Research Laboratories, I.C.I., Ltd.

Thursday

- BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, London, W.—January 17, 8 p.m., "The Radiological Diagnosis of Intracranial Tumours in Children," by Dr. J. W. D. Bull.
- BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 17, 5.30 p.m., "Fundamentals of Cortical Physiology," by Sir Geoffrey Jefferson, F.R.S.
- EDINBURGH CLINICAL CLUB.—At B.M.A. Rooms, 7, Drumsheugh Gardens, Edinburgh, January 17, 8 p.m., "The Treatment of the Menopause," by Dr. T. N. MacGregor.
- LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool.—January 17, 8 p.m., ordinary meeting. "Our Heritage—the Origin and Development of the Liverpool Medical Institution," by Mr. W. A. Lee.
- LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Medical Society of London, 11, Chandos Street, W., January 17, 8.30 p.m., "The Nutritional Assessment of the Individual," address by Professor John Yudkin.
- ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—January 17, 5 p.m., "Some Concepts of Rheumatic Disease," Goulstonian Lecture by Dr. J. H. Kellgren. (See also January 15.)
- ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—January 17, 5 p.m., "Corneal Infections and their Specific Treatment," ophthalmology lecture by Professor Arnold Sorsby.
- ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At 26, Portland Place, London, W., January 17, 7.30 p.m., ordinary meeting. "The Treatment of Leprosy with D.D.S.," by Dr. Ernest Muir; "The Action of Sulphones in Leprosy, with Particular Reference to Histopathology," by Dr. R. G. Cochrane. A discussion will follow.
- ST. ANDREWS UNIVERSITY.—At Lecture Theatre, Materia Medica Department, Medical School, Small's Wynd, Dundee, January 17, 5 p.m., "The Application of the Electron Microscope to Bacteriology," by Dr. J. E. McCartney, D.Sc.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—January 17, 4.30 p.m., lecture-demonstration in psychiatry by Sir Paul Mallinson.

UNIVERSITY COLLEGE, Anatomy Theatre, Gower Street, London, W.C.—January 17, 1.15 p.m., "What is Pharmacology?" by Dr. H. O. Schild.

Friday

- BRITISH INSTITUTE OF RADIOLOGY, 32, Welbeck Street, London, W.—January 18, 5 p.m., meeting of medical members.
- FACULTY OF RADIOLOGISTS.—January 18, (1) at Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., 4 p.m., meeting of Radiotherapy Section. "The Clinical Features and Types of Intracranial Tumours Found in Children," by Professor Norman Dott; "The Combined Roles of Surgery and Radiotherapy in the Treatment of Intracranial Tumours in Children," by Mr. John Gillingham; "The Pathology of Intracranial Tumours in Children," by Dr. Martin Bodian. (2) At Royal Society of Medicine, 1, Wimpole Street, London, W., 8.15 p.m., "The Diagnosis and Radiotherapy of Intracranial Tumours in Children," by Mr. J. Jackson Richmond and Dr. Edith Paterson; "The Treatment of Megaloblastoma," film by Dr. Edith Paterson.
- INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 18, 5.30 p.m., "Medical Writing," by Dr. W. R. Bett.
- INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF RADIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 18, 5.30 p.m., "Surgery of the Heart: Techniques of Investigation," by Dr. Aubrey Leatham.
- ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—January 18, 8 p.m., "The Curious Effects of Carbon Monoxide Poisoning," by Dr. James K. Slater.

Saturday

- BIOCHEMICAL SOCIETY.—At Middlesex Hospital Medical School, London, W., January 19, 10.30 a.m., 304th meeting. Scientific papers will be read.

APPOINTMENTS

The King has appointed Dr. George Brewster to be Surgeon-Apothecary to the Household at Holyroodhouse Palace in succession to Dr. N. S. Carmichael, deceased.

Dr. Vernon Frederick Hall, Dean of King's College Hospital Medical School, London, S.E., has been appointed a member of the South-east Metropolitan Regional Hospital Board in succession to the late Mr. J. B. Hunter.

COUSINS, B. A., M.Sc., M.B., B.Ch., Medical Registrar, Norfolk and Norwich Hospital, East Anglian Regional Hospital Board

CRAIG, C. McK., Junior, M.B., B.S., F.R.C.S., Consultant Surgeon to Lowestoft Hospital, Norfolk and Norwich Hospital Group, East Anglian Regional Hospital Board

DIVILLY, PATRICK JOSEPH, L.R.C.P.&S.I., L.M., Medical Officer, Feakle Dispensary District, Co. Clare, Eire

INMAN, G. K. E., M.B., Ch.B., D.M.R.D., Senior Registrar in Radiology to Bristol Clinical Area, South-western Regional Hospital Board

LEWIS, T. L. T., M.B., B.Ch., F.R.C.S., M.R.C.O.G., Obstetric Surgeon, Queen Charlotte's Maternity Hospital, Goldhawk Road, Hammersmith, London, W.

LIVERPOOL REGIONAL HOSPITAL BOARD.—Senior Resident Medical Officer at New Hall Hospital, Southport, R. S. Cook, M.B., Ch.B. Whole-time Assistant Radiologist to Hospitals in St. Helens and Warrington Areas, A. Attwood, M.B., B.Ch., D.M.R.D. Part-time Consultant Dermatologist to Clatterbridge General Hospital, D. G. Freshwater, M.B., B.Ch., M.R.C.P. Consultant Physician to Clatterbridge General Hospital, M. W. Wood, M.D., M.R.C.P.

MACLACHLAN, JAMES, M.B., Ch.B., D.P.H., Medical Officer of Health and Port Medical Officer, County Borough of Barrow-in-Furness, and School Medical Officer.

MANCHESTER REGIONAL HOSPITAL BOARD.—Consultant General Physicians, Crumpsall Hospital, Manchester, M. D. Milne, M.D., M.R.C.P., R. V. Dent, M.B., B.Ch., M.R.C.P. Consultant Obstetrician/Gynaecologist, Withington Hospital, Manchester, R. W. Burslem, M.D., M.R.C.O.G.

MOORE, ROBERT, M.B., B.S., M.R.C.P., Senior Medical Registrar, St. Andrew's Hospital, Devons Road, London E.

ROUTLEDGE, R. T., M.B., B.S., F.R.C.S., Senior Registrar in Plastic Surgery, Bristol Clinical Area, South-western Regional Hospital Board

SOUTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD.—Consultant (Assistant) Obstetrician and Gynaecologist, Portsmouth Group of Hospitals, J. J. Foley, M.B., B.Ch., M.R.C.O.G. Whole-time Consultant Physician, Portsmouth Group of Hospitals, F. H. Minors, M.B., Ch.B., M.R.C.P., D.C.H. Part-time Consultant Physician, Chelsea Group of Hospitals, R. T. Foley, M.D., M.R.C.P. Part-time Consultant Physician for Chest Diseases, Chelsea Group of Hospitals, L. J. Grant, M.B., B.S., M.R.C.P. Whole-time Physiotherapist and Consultant Psychiatrist, Netherne Hospital, R. K. Freudenburg, M.D., D.P.M. Whole-time Consultant Child Psychiatrist, Hampshire Child Guidance Service, Daisy G. Iltis, M.R.C.S., L.R.C.P., D.P.M. Whole-time Consultant Anaesthetist, Woking and Chertsey Group of Hospitals, Eileen McC. Gibson, M.B., B.Ch., D.A. Part-time Consultant Anaesthetist, Isle of Wight Group of Hospitals, R. T. V. Clarke, B.M., B.Ch., D.A. Part-time Consultant Ophthalmologist, Fulham and Kensington Group of Hospitals, P. L. Blaxter, M.B., B.Ch., F.R.C.S., D.O.M.S. Part-time Assistant Thoracic Surgeon, Godalming, Milford, and Liphook Group of Sanatoria, C. E. Drew, M.B., B.S., F.R.C.S. Part-time Consultant Surgeon, Woking and Chertsey Group of Hospitals, M. T. Pheils, M.B., B.Ch., F.R.C.S.

Part-time Consultant Radiologist, Woking and Chertsey Group of Hospitals, R. O. Murray, M.B. B.Chir., D.M.R. Whole-time Assistant Chest Physician (S.H.M.O. Grade), Dorset and Poole Areas, A. E. K. Salvi, M.R.C.S., L.R.C.P. Whole-time Assistant Chest Physician (S.H.M.O. Grade), Southampton Area, Mary F. Brownlie, M.B. Ch.B., D.P.H. Consultant Chest Physician, Southampton Area, W. M. MacLeod, M.B. B.S., M.R.C.P., Registrar (Orthopaedic Surgery), Croydon Group of Hospitals, G. M. Bedbrook, M.B. B.S., F.R.C.S., F.R.A.C.S. Registrar (Anaesthetics), Salisbury General Hospital, V. P. Wordsworth, M.R.C.S., L.R.C.P. Registrar (Anaesthetics), St. Luke's Hospital, Guildford, Kathleen J. Logan, M.B. Ch.B. Registrar (Obstetrics and Gynaecology), Nelson Hospital, I. M. G. Mackay, M.R.C.S., L.R.C.P., D.Obst. R.C.O.G. Registrar (Infectious Diseases), Western Hospital, S. Y. To, M.B. B.S., D.T.M. & H. Registrar (Medical Department), Milford Chest Hospital, Eudora M. R. Davies, M.B., Ch.B. Senior Registrar (Psychiatrics), Brookwood Hospital, E. R. F. Mellon, M.B. B.Ch., D.P.M., D.P.H. Registrar (Psychiatrics), West Park Hospital, R. D. Watson, M.B., B.S. Registrar (Psychiatrics), Cassel Hospital, W. A. Saffery, M.B. B.Ch.

WILLIAMS, D. LLOYD, L.R.C.P.&S. Ed., L.R.F.P.S. (Glasg.), Assistant Medical Officer of Health and Assistant School Medical Officer for the County of Merioneth.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Harris-Jones.—On December 23, 1951, at Sheffield, to Carol (formerly Mackenzie), wife of J. N. Harris-Jones, M.D., M.R.C.P., a sister for Richard (George).

Marrinan.—On December 31, 1951, at Cambridge, to Biddy Kingsley Pillers, M.B., B.Chir., wife of Denis H. Marrinan, a son.

Mathers.—On December 22, 1951, at the Military Hospital, Malta, to Diana (formerly Mould), wife of Dr. George C. Mathers, a son.

Thomas.—On December 28, 1951, at the Maternity Hospital, Royal Infirmary, Preston, to Morfudd (formerly Humphreys), M.B., Ch.B., wife of Dr. William M. Thomas, a second daughter.

Wilson.—On January 2, 1952, at the South London Hospital for Women, to Agnes Christian (formerly Gillan), O.B.E., M.B., Ch.B., wife of William Proctor Wilson, C.B.E., B.Sc., M.I.E.E., a son.

DEATHS

Adam.—On December 26, 1951, at 10, Russell Place, Edinburgh, James Robertson Adam, M.B., Ch.B., D.P.H.

Aldous.—On January 3, 1952, Herbert James Aldous, L.S.A., L.R.C.S. Ed., of Boundary Stone, Paulsgrove, Portsmouth, Hants, aged 76.

Anderson.—On December 26, 1951, at 70, Wadsley Lane, Sheffield, Alexander Anderson, M.B., C.M., D.P.H., aged 84.

Benson.—On December 28, 1951, in Somerset, Wallace Benson, C.B.E., D.S.O., M.B., B.Ch., Colonel, A.M.S., retired.

Bulleid.—On December 27, 1951, at his home, Dymhoro, Midsomer Norton, Somerset, Arthur Bulleid, L.R.C.P.&S. Ed., L.R.F.P.S., aged 89.

Carr.—On December 30, 1951, at Woodhouse, Windsor Road, Gerrard's Cross, Bucks, Mona Carr (formerly Kirkhouse), M.D.

Cock.—On December 29, 1951, at his home, 7, Gipsy Hill, Upper Norwood, London, S.E., Gerald Cock, M.R.C.S., L.R.C.P.

Davies.—On December 28, 1951, at his home, 2, Morfa Lane, Carmarthen, Arthur Lewis Davies, M.R.C.S., L.R.C.P.

Dickenson.—On January 6, 1952, at Newshott, Haslemere, Surrey, George Oswald Morrell Dickenson, M.B., B.S., Surgeon Captain, R.N., retired.

Ferguson.—On December 29, 1951, at St. Andrews, Joshua Ferguson, M.B., C.M., L.R.F.P.S., of 11, Windmill Road, St. Andrews, Fife, aged 80.

Geraghty.—On January 3, 1952, at the Manchester Royal Infirmary, William Geraghty, M.B., Ch.B., of "Glenesk," Ashton Lane, Sale, Cheshire, aged 54.

Jackson.—On December 28, 1951, at Plas Uchaf, Penmaenmawr, Caernarvonshire, Robert Jackson, T.D., M.B., C.M., Colonel, A.M.S., T.A., retired, aged 89.

Jameson.—On December 26, 1951, at Queen Victoria Hospital, East Grinstead, Surrey, George Dearden Jameson, M.R.C.S., L.R.C.P., D.P.H., Lieutenant-Colonel, R.A.M.C., retired, of Chilling Street Cottage, Sharpthorne, Sussex.

Kohn.—On December 15, 1951, at 62, Alexandra Road, Wimbledon, London, S.W., Elizabeth Kohn, M.B., B.S., M.R.C.P. Ed., late of Rangoon, Burma.

Lys.—On December 29, 1951, at Emo Lodge, Bournemouth, Henry Graham Lys, M.D., M.R.C.P., aged 87.

MacGibbon.—On January 3, 1952, at 30, New North Road, Huddersfield, Robert Robertson MacGibbon, L.R.C.P.&S. Ed., L.R.F.P.S., aged 52.

Maillet.—On January 2, 1952, at 5, South Close, Highgate, London, N., William Maillet, M.B., C.M.

Malone-Barrett.—On December 26, 1951, at Aveland, East Dean, Eastbourne, Sussex, Francis Malone-Barrett, M.B., B.Ch.

Miller.—On January 1, 1952, at a nursing-home, Edinburgh, Ada Elizabeth Miller, M.D., D.P.H., of 6, Cobden Road, Edinburgh.

Miller.—On December 31, 1951, William Henry Miller, M.D., F.R.C.S., of 43, St. Peter's Street, Bedford, aged 70.

Nix.—On December 31, 1951, at Chatteris, Cambs, Rupert Edward Nix, M.B., B.Ch., J.P., aged 84.

Peace.—On January 1, 1952, at Tellisford, Burry Port, Carmarthen, Percy Clift Peace, M.R.C.S., L.R.C.P.

Peake.—On January 4, 1952, at his home, "Keeps," Hillside, Horsham, Sussex, William Pemberton Peake, T.D., M.R.C.S., L.R.C.P.

Richmond.—On December 16, 1951, Henry Richmond, M.B., Ch.B., D.P.H., of 314, Wigan Road, Standish, Wigan, Lancs, aged 64.

Robbins.—On December 25, 1951, in London, Frank Hubert Robbins, M.C., M.B., F.R.C.S. Ed., aged 64.

Skeels.—On January 5, 1952, in London, Percy Bernard Skeels, L.M.S.S.A.

Smith.—On December 26, 1951, at Stronsay, Wickham, Co. Durham, Edward Davison Smith, M.B., B.S., aged 67.

Smyth.—On December 26, 1951, at Buxton, Richard Smyth, M.D., M.Ch., formerly of Ningpo, China, aged 88.

Willson.—On January 4, 1952, Reginald John Willson, M.B., B.Ch., D.P.H., of Newlands, Carlton Road, Redhill, Surrey, aged 77.

Wilson.—On December 29, 1951, at Finchley, London, N., Helen Mary Wilson, M.D., J.P., formerly of Sheffield, aged 87.

Wyllie.—On December 17, 1951, at 10, York Gate, London, N.W., Hugh Alexander Wyllie, M.B., B.S.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

How to Test Schoolchildren's Hearing

Q.—What tests for hearing are recommended for the routine medical inspection of schoolchildren? What result with each would you consider an indication that the child required treatment for deafness?

A.—An ideal test for this purpose involves the use of a gramophone audiometer which replays over headphones a randomized list of single digits or simple words at intensities decreasing in about 3-decibel steps. Up to 40 children may be tested simultaneously by this means. An average hearing loss of 10 decibels in one or both ears should be considered as an indication of requirement of further investigation. Another test, which is very satisfactory, is known as the "sweep frequency test." This consists in setting the output intensity of a pure-tone audiometer at a very quiet level—say that corresponding to a hearing loss of 10 decibels—and seeing if the child responds to the various tones at this level. Failure to respond to two or more tones can be considered as indicating further investigation.

A less efficient but, for reasons of economy, frequently chosen method is the measurement of the maximum distance at which each ear can hear forcibly whispered numbers or simple syllables, the untested ear being closed with a finger and turned away from the examiner. The child is asked to repeat the words heard, and if the maximum distance for 90% success is 20 ft. (6 metres) or more the ear under test may be regarded as normal. Particular attention should be given to the child's hearing for consonants. It must be remembered that the presence of background noise in the test-room will raise the threshold of hearing by an amount dependent on the level of the disturbance, and this should be borne in mind in interpreting results. The acoustic properties of the test-room also contribute to the unreliability of the test.

Should one of these tests indicate subnormal hearing, the child should be further examined by an otologist, who will, if the deafness is confirmed, advise upon the question of treatment.

Any information such as difficulty in hearing the teacher's voice in the classroom should be taken into consideration. Serious retardation of speech development may, though not always, be an indication of some degree of hearing loss, particularly to high frequencies.

Thumb-sucking

Q.—Where can I find information on the management of a child who sucks his thumb?

A.—On p. 194 of the book "Any Questions?" The book can be obtained for 7s. 6d. (postage 6d.) from the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1.

Discoid Lupus Erythematosus

Q.—What is the best treatment for discoid lupus erythematosus of the scalp in an elderly woman? What is the prognosis?

A.—The cause of discoid lupus erythematosus is unknown and there is no specific therapy. The condition may be influenced by any other organic or functional state which may be present, and this should receive attention. If there is no contraindication, gold therapy is valuable and may cure or arrest progress of the disease. Mepacrine in a dose

of 100 mg. twice a day was more effective than other measures in a series of cases recently reported.

The prognosis is bad in the sense that the condition destroys skin and hair and produces an irreversible, scarring alopecia. The disease does not affect the general health. If extensive, ulceration sometimes occurs, which generally responds to small doses of sulphonamide by mouth and locally, but this treatment must be used with care. Malignant changes are rarely seen.

Prognosis in Retinitis Pigmentosa

Q.—*What is the outlook for a boy of 10 who has retinitis pigmentosa (diagnosed by two eye specialists)? Difficulty of vision, only in the dark, was first noticed six years ago after an attack of kala azar treated by antimony. The parents have been told that the child will eventually become blind. How quickly will this happen?*

A.—The development of nightblindness in retinitis pigmentosa as early as the age of 4 is unusual; so also is a diagnostic fundus appearance at the age of 10. This in itself raises doubt whether one is dealing with the classical form of hereditary retinitis pigmentosa, though such early changes may occur in the severe, but rare, sex-linked type. A full family history is needed, and also information on whether the boy shows the characteristic field defects of retinitis pigmentosa. If the boy is actually suffering from genetically determined retinitis pigmentosa there is no treatment, and it is impossible to indicate how rapidly his vision will deteriorate. If his affection is of the sex-linked type, serious trouble is almost certain by the age of 25 years.

The history of kala azar treated by antimony may be significant. With the unusual findings in this case it is possible that the nightblindness and pigmentary changes were precipitated by either the infection or the treatment. The picture of retinitis pigmentosa has been observed in measles, after vaccination, and after quinine treatment of malaria. In these cases the tendency is for some improvement rather than deterioration.

Angina and Cold Weather

Q.—*A woman of 56, who has angina, has an opportunity to go to Ontario, where the winter climate is cold and dry. Will this be likely to precipitate her anginal attacks, which are often brought on here by cold nights?*

A.—Although Sir Thomas Lewis was unable to demonstrate that cold played any part in precipitating attacks of angina pectoris, general experience has shown that it does. There is no doubt that cold may raise the blood pressure in susceptible individuals, and this may help to provoke an attack by increasing the work of the heart. In the particular case in question it seems clear that cold is harmful, and the patient would surely be unwise to go to Ontario.

Cytochrome c and Carbon Monoxide Poisoning

Q.—*What are the functions of cytochrome c? It has been suggested that it might be a useful analeptic for cases of carbon monoxide poisoning after mining accidents. Is there a sound basis for this view?*

A.—Cytochrome c is a respiratory catalyst which is required for the utilization of the oxygen reaching the tissues from the blood. In carbon monoxide poisoning, less oxygen reaches the tissues because some of the haemoglobin, the respiratory carrier in the blood, is combined with carbon monoxide. The question is probably inspired by a report that cytochrome c is beneficial in conditions of anoxia. Exhaustive trials in many laboratories have failed to confirm this report. In any case, even if cytochrome c could increase the rate of utilization by the tissues of the limited amount of oxygen reaching them in carbon monoxide poisoning, this would probably be more harmful than useful, since the oxygen would be depleted more rapidly. Cytochrome c does not combine with carbon monoxide, so it is useless as a direct antidote.

Camphorated Oil

Q.—*Am I right in believing that rubbing the chest with olive oil or camphorated oil, or any other preparation, serves no useful purpose and may even be harmful in the treatment of an infant or child suffering from bronchitis?*

A.—Unless the rubbing is over-vigorous or prolonged or the preparation too strong, in which case dermatitis may follow, no harm is likely to result from the use of a medicated oil in cases of bronchitis. On the other hand, no great therapeutic response can be expected; the counter-irritation may be of some slight value, and in the case of an oil or ointment containing menthol or camphor some inhalation of vapour will follow, and this may be helpful in clearing the upper air-passages.

Pills for Bankrupt Smokers

Q.—*I have tried to purchase locally from many chemists some pills which are sold for the prevention of smoking, but I have been unable to buy them or find a formula for their preparation. The pills I have in mind are normally dissolved in the mouth, and, while being quite tasteless themselves, produce a very nasty taste if the subject tries to smoke a cigarette. I would be grateful if you could tell me their formula.*

A.—The formula of the pills is as follows: dried sulphate of iron, 67.85%; potash alum, 17.85%; lactose, 14.28%; acacia, 0.75%; green colouring matter and excipient, q.s. They should be kept out of the reach of children.

Speedy Hypnotic

Q.—*What sedative has the quickest and shortest action when taken orally?*

A.—The hypnotics with the quickest and most evanescent action are probably pentobarbitone sodium and sodium propylallylbarbiturate. There is not much to choose between them. The dose is from 1½ to 3 gr. (0.1 to 0.2 g.). They are effective within half an hour, and are certainly not active for longer than six hours.

Lymph Drainage of Nasal Sinuses

Q.—*What is the lymphatic drainage of the accessory air sinuses? I have been unable to find information about this in standard anatomical and surgical textbooks.*

A.—The best account may be found in *Histopathology of the Ear, Nose and Throat* by Eggston and Wolff (Williams and Wilkins, Baltimore, 1947). Quoting papers by J. M. Robison (*Tex. J. Med.*, 1944, 40, 193; *Arch. Otolaryng.*, Chicago, 1944, 40, 385), these authors state that drainage is probably to a pretubal lymph plexus, thence to lateral retropharyngeal lymph nodes, and partly to submaxillary nodes, and so to the deep cervical chain.

NOTES AND COMMENTS

Honours List: Correction.—Mr. CHARLES E. DREW, who became M.V.O. in the New Year Honours, is a member of the consultant staff of the Westminster Hospital, having been appointed as fourth assistant surgeon on April 9, 1951. We regret that this hospital appointment was incorrectly given in last week's *Journal* (January 5, p. 44).

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: *Atiology, Westcent, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad. ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. HOUSE, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.). TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads, Westcent, London*. MEMBERS' SUBSCRIPTIONS should be sent to the SECRETARY of the Association, TELEPHONE: EUSTON 4499. TELEGRAMS: *Medisecra, Westcent, London*. EXECUTIVE COUNCILS AND THE PROFESSION*

BY

S. WAND, M.B., Ch.B.

The Acts which inaugurated the National Health Service made provision for different administrative machines in the various sections of that Service. Much was new and founded on discussion and anticipation. But executive councils were new almost only in name. They were the successors of the insurance committees. These had developed by a process of evolution. Trial and error, experience, wisdom, argument, and dispute had all played their parts. That is as it should be, and it is of more than academic interest to note that executive councils have come in for less criticism and more praise than any other administrative body in the Service. In fact there are many who believe that their general structure should be more widely used.

Liaison Committees

I have noted with great satisfaction that some executive councils have taken positive steps to effect the fullest liaison between the three sections of the Service—general practitioner, hospital, and public health. In discussions before the passing of the Acts the medical profession expressed on many occasions its anxiety on this point. I believe it was expected in official quarters that this co-ordination would be effected in practice by the user; and executive councils, as the bodies closest to the consumer interest, can play a most important part in consultation with medical committees. The long-term policy, the question of modification of existing structures, and the methods of co-ordination are engaging the active attention of the profession, but in the interim the executive councils can and should promote the fullest co-operation. Much valuable experience of method will be obtained.

An example that readily springs to mind is the exchange of information on the hospital bed position and the potential

demand from the periphery. Last winter we were shown the need for this during the influenza epidemic. Another example is in the field of preventive medicine—inoculation and vaccination.

A multiplicity of liaison committees, however, with necessarily the same people serving, should be avoided so far as possible. The number of committees, and the work of those committees, has increased in an alarming measure and shows few signs of diminishing. It is important to avoid a situation in which committee members have to devote so much time to committee work that only the semi-retired can do it.

So far as doctors are concerned it is of the greatest importance that those who serve on committees should have the most up-to-date practical knowledge and that the younger man should be there to express his views and state his difficulties.

Feeling of Frustration

That there have been many expressions of frustration by the doctors in the National Health Service is common knowledge. It is interesting to note that the word constantly used has been "frustration." The reasons are not far to seek. Apart from the questions of finance and status, which are to be dealt with elsewhere, this frustration arises because the doctor is so often prevented from doing the best and most useful work of which he is capable. Before the Service began doctors were promised an easier life for their families and themselves, and particular stress was placed on the point that they would be able to lead a fuller and more useful professional life. In fact it was this expectation that decided very many doctors to enter the Service.

The general practitioner believes, I think rightly, that he is the most important person in the organization of a health service. He believes that no occupation is so satisfying as good general practice carried on in a proper way with the fullest two-way confidence and understanding between his patient and himself.

This was the promise. Has it been implemented? The answer is, "No." The reasons are plain to see. There has been a substantial increase in the items of service provided. The increase in hours of work has been even greater. There has been a change in the

*An address, here slightly shortened, delivered on October 11, 1951, at the Fourth Annual Meeting of Executive Councils Association (England).

relationship between general practitioner and patient, in many cases not for the better. We hear on all sides of unreasonable demands made by a small minority; stories, well substantiated, of a great increase in the number of calls asked for, particularly those asked for at the wrong end of the day for no proper reason. Indeed, many such calls are not asked for; they are demanded with abuse; and I have had reported to me cases of actual violence by the patient against the doctor because the doctor asked for some further information. The doctor has no redress except in the ordinary courts, but a hasty word by a tired doctor can, and does, lead to a medical service committee inquiry, with all its anxieties to the doctor and possible publicity.

Have executive councils any responsibility, by acts of commission or omission, for the state of affairs I have indicated? I think that they have. Executive councils have facilities for bringing to the notice of the Press much that could be of value, yet most reports of executive council meetings are confined to juicy medical service committee cases and finance.

Consider Your Doctor

This is a new service. Its efficiency, indeed its very existence, depends upon the use made of it. The users must be educated, conditioned to it. They must be made to understand that it is theirs and therefore they must cherish it and use it prudently, thinking not only of themselves but of their fellows. "Use your Service properly. It is your Service." "Consider your doctor. He is human, too." "Use your doctor wisely. You may need him yourself some day." Such thoughts which I have presented in slogan form could form the basis of such an education.

The type of publicity attaching to executive council reports up to the present has so far had the effect only of emphasizing to the public their right of making complaints. How much more useful would my suggestion be?

It may be that the life of a general practitioner is not sufficiently known in detail. It would not be amiss at this stage in the growth of the Service to set out in brief a doctor's day. First and foremost it is the same doctor who does the morning surgery, the morning visits, the afternoon visits, the evening surgery, the evening visits, the late visits, and the night visits, who is disturbed by the telephone, often most unreasonably, at meal times seven days a week, week in, week out. This same doctor has to find time to write his case notes, his letters, to read to keep abreast of current literature. He is always expected to be 100% efficient, 100% alert, 100% courteous. His family has to carry a big burden to maintain a 24-hour service in these days of difficulty with domestic staff. It is a very great anxiety to do this. His opportunities for social and family life are few and disturbed, and it is one of the basic factors in current thought that a man must have adequate leisure.

Work in the 70th Hour

He knew all this when he went into general practice, but difficulties have increased. Whatever the size of his list, whatever his age, whatever the state of his health, if he is at work, he must give the full 24-hour service. In one country in which statistics were recently prepared it was found that the expectation of life of a doctor was 15 years less than that of the average of the

population. It will not help the public if this gap is widened. The public itself will be the main sufferer if the doctor is overtired unnecessarily.

Let us take one example—the late call. It is not realized that a call that comes after the doctor has started on his morning round cannot easily be done until the afternoon, or that one coming in after he has started his afternoon round may not be possible until after he has finished a very heavy evening surgery (I am, of course, excluding the emergency for which everything is dropped). In the winter this is often a hard three- to four-hour session started when he has already done an eight-hour day. Picture, then, the doctor, after a heavy 11- or 12-hour day, as so often happens in the winter, having to get out his car and drive on a winter's night over ground he has covered already, perhaps many times, that day, to find that the message could quite easily have been sent at the proper time, or, in fact, that a visit was not at all necessary—the patient could have come to surgery. It is a serious waste of valuable professional time.

In these days of the 40-hour week, how are you to assess in terms of wear and tear on the doctor the work done in the 70th hour?

Here, then, is part of the frustration. To know that you can be of help to those who suffer, to want to give that help and to be prevented by unreason on the part of those whom you wish to help, is particularly annoying, fatiguing and irritating, and here the executive councils could help. Sympathy and understanding of the work and difficulties of the general practitioner by the non-medical members of the executive councils is the prerequisite, its dissemination to the public the natural sequel.

Unreasonable Complaints

I have mentioned only a few points and examples. I could have mentioned cases of the grossest abuses which could, in National Health Insurance days, have been dealt with by a complaint from the doctor. The doctor can no longer lodge a complaint. But even under present regulations it is not impossible for the executive councils to bring to the notice of those who misbehave the folly of their actions.

The very doctors who are most conscientious are those who are likely to get most fatigued and irritable, and the general practitioner should be protected against the trivial and unreasonable. The machinery of the medical service committee once started is bound to cause the greatest anxiety to the doctor and is detrimental to the quality of his work. If such machinery has to be put into operation, let it be as speedy as possible, even to the extent of calling special meetings of the committees.

Executive councils are bodies honoured and respected in their areas. They have the ear of the Press. If they want to create better understanding, let their thoughts constantly be along the lines, How can we help the doctor to help the patient?

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Southwark, Stoke Newington.

Non-County Borough Councils.—Crewe.

Urban District Councils.—Droylsden, Houghton-le-Spring, Huyton-with-Roby.

GENERAL MEDICAL SERVICES SUBCOMMITTEE (SCOTLAND)

At the first meeting of the new session of the General Medical Services Subcommittee (Scotland), Dr. J. T. BALDWIN (Milton Bridge) was appointed chairman in place of Dr. W. M. KNOX (Glasgow), whose period of office had expired. Dr. Baldwin, in accepting office, stated that in normal circumstances the chairman would have been Dr. W. JOPE, the former vice-chairman of the Subcommittee, but owing to health reasons Dr. JOPE had decided to resign from the chairmanship of the Conference of Local Medical Committees and not to seek re-election to the G.M.S. Committee; consequently, he was not a member of the Scottish Subcommittee. The Subcommittee expressed appreciation of the work done on behalf of the profession by Dr. JOPE and Dr. KNOX and congratulated Dr. KNOX on his appointment.

Dr. C. J. SWANSON, Aberfeldy, was appointed vice-chairman. Appointments were also made to the various subcommittees for the ensuing year.

The Subcommittee considered further the proposal of the Department of Health to appoint to the general medical services part of the National Health Service regional medical officers for the purpose of liaison with the other branches of the profession and to assist in the routine day-to-day administration.

Inflation of Lists

There was also considerable discussion on the question of the reinstatement on doctors' lists of persons who have been abroad, and the removal from those lists of persons going abroad for a short period only, together with the general question of inflation of lists.

The view of the Subcommittee was that the onus of notifying change of name and/or address should be placed on the patient, and it was agreed to discuss with the Department of Health the possibility of having a note to this effect incorporated on the medical card.

PRIVATE PRACTICE COMMITTEE

FEE REVISIONS

A meeting of the Private Practice Committee of the Association was held on January 2. In the absence of the chairman, Dr. I. D. GRANT, Dr. ROBERT FORBES was voted to the chair.

It was reported that the Air Ministry had agreed that in view of the attitude of the Association it had no alternative to the payment of a fee of 1 guinea for examination for fitness for gliding. Previously the fee was 5s.

The British Employers' Confederation had agreed to meet the Committee's representatives to discuss certificates of incapacity required by employers; the meeting had been arranged for January 8.

The details of the revised scale of fees for practitioners called in by the police had been circulated to police authorities and to Branch and Division secretaries. A number of chief constables had asked for additional copies of the scale.

A conference had taken place with the Home Office on the proposed new procedure for cremation certificates at which criticism of the scheme was made. The final views of the Home Office are now awaited.

Part-time Work under Local Authorities

The Committee discussed the revised fees for part-time work under local authorities—a proposed revision of the 1947 agreement which had been under discussion by the

Public Health Committee. The proposals met with general concurrence, and the Private Practice Committee recommended that the revision be negotiated through the Whitley machinery.

It was stated that a "catastrophe service" scheme was being prepared by the chief constable of Derby, with a view to ensuring the attendance of trained personnel in the event of a serious railway accident in the vicinity of that town. The Derby Medical Committee, which had been informed of this project by the chief constable, had asked for advice and suggested that this was a national rather than a regional problem. It was agreed to discuss the matter with the chief medical officer of British Railways.

For the completion of a certificate under the appropriate section of the Coal Mines Act, 1911, as to the eyesight and hearing of firemen, examiners, and deputies—the customary fee for which was said to be 5s.—the Committee decided that the appropriate fee would be 10s. 6d. for the first case of a series and 7s. 6d. for subsequent cases.

A protest is to be made against a proposal by the Ministry of Labour to increase the number of recruits called to attend National Service Boards.

The Committee considered certain principles of medical certification put forward by the World Medical Association. The chairman of the Ethical Committee stated that in the view of his committee only the first of the ten—which concerned professional secrecy—came within its province. The others were concerned with accuracy, objectivity, and the like. The Private Practice Committee, while not prepared to commit the profession to all the principles, took no exception to any of them, but it suggested that one of them—namely, "The statements in a certificate should be sufficient to achieve its purpose"—required further elucidation.

Tribunals and Written Evidence

The question of written evidence submitted to tribunals set up under the Dangerous Drugs Regulations had previously exercised the minds of the Committee, and the opinion of the solicitor of the Association had been sought. The solicitor said that as a lawyer he had an instinctive dislike for all evidence other than oral, on which the witness could be cross-examined, but he agreed that to insist on oral evidence in all cases, whether the evidence was likely to be challenged or not, meant inconvenience to doctors who were required to give it, and might preclude a respondent, when it was a question of drug addiction, from putting in a medical certificate to the effect that he had been cured.

The Committee adhered to its objection to written evidence, but modified its view to the extent that evidence which was agreed by both sides might go forward in the written form without the personal appearance of the witness.

Retired Pay Posts

It was reported that discussions with the War Office and other interested departments on the revised conditions of service and increased rates of pay for retired medical officers were well advanced, but that the new scheme was not likely to be promulgated for some months. It had been pointed out that this meant considerable hardship to several practitioners in that their salary, in addition to pension, was restricted to £428 a year, and the War Office had now agreed to increase the annual rates of pay for retired medical officers employed as full-time civilian medical practitioners to £650 in London, £635 in the provinces, and £620 elsewhere.

Cars for Doctors

Dr. A. WESTON, of Greenford, attended the Committee by invitation to put forward some suggestions for a revised scheme for the preferential delivery of doctors' cars. He

considered the present position was unsatisfactory and suggested that a scheme was badly needed which would enable a doctor to replace a car which was no longer reliable for his professional work.

Dr. L. S. POTTER, Assistant Secretary, said that there were some points in such a scheme which would require careful examination. The implication was that there would be a pool of cars which would go to members of the medical profession. But would the profession take kindly to a method of allocation whereby if a doctor refused the car offered to him he would lose any further priority? No arrangement was entirely satisfactory. After a long experience he could not conceive of any scheme on paper which would not permit of possible evasion and abuse, but he thought there were dangers in recasting the present scheme, in which they had the co-operation of the manufacturers.

It was decided that Dr. Potter should prepare a detailed memorandum for the next meeting of the Committee, to which Dr. Weston was invited, and the whole matter could then be fully discussed.

THE HEALTH SERVICE IN INFLATION

[FROM A SPECIAL CORRESPONDENT]

This is the season of the year when Government departments are preparing their annual estimates for the coming financial year and the Treasury is as busily asking them to cut their estimates down. It can be taken for granted that this year the axe will be wielded more severely than it has been for some time. Not only is there a new Government in office which is pledged to make savings on administrative costs, there are also the hard facts of the economic situation.

At the end of last week the Treasury announced large increases in salary for non-industrial Civil Servants. Some 600,000 benefit from the increases, which will cost about £30m. a year. Even so, the new rates do not affect Civil Servants earning £1,500 and over, for whom a separate claim has been submitted but not yet decided. Nor do they give the Civil Servants to whom they do apply full compensation for the rise in the cost of living as measured by the index of retail prices. But the increases, which will mean an extra £80 a year for a Civil Servant earning £1,200, do reflect, according to the Treasury, wage increases that have taken place during the past year in outside industry while Civil Service pay was unchanged.

Wage Increases

Information on these increases in wages was given in the *Ministry of Labour Gazette* for December, 1951. In the first 11 months of 1951 some 12 million workpeople received increases amounting to £5,940,000 a week. In November alone about three million people received increases amounting to £1,419,000 a week. In the whole of 1950 the increase in weekly wage rate was only £2m. In the autumn of that year, however, the wage freeze, which had been slowly melting for some time, gave way altogether. Since then, as can be seen from the accompanying Table, the index of wage rates has been slowly climbing point by point, jumping three points in November, 1951.

1950:			September	121	
June	110		October	122	
December	114		November	125	

Compared with the Civil Servants' £30m. a year, the increases to workers in the engineering and shipbuilding trades will cost about £78m. The railway workers received an increase in November which will cost £14m. a year; but this is in addition to the award made last February, which cost £12m. Nor do the November figures take into account the recent increases to coalminers, which will cost about £26m. a year. The increases in wage rates granted in 1951 will in fact raise the wage bill by well over £300m. a year.

Even this is not the whole story, for all the figures given are for wage rates, not for earnings, which are affected by overtime or short time. No earnings figures are available for a later date than April, 1951. They then showed an increase of 156% on 1938, compared with an increase of 140% in October, 1950, and 133% in April of that year.

Prices and Wages

It was only to be expected, once wage restraint was abandoned, that the trade unions would attempt to catch up with the rise in the cost of living, which was being steadily pushed upwards as a result of devaluation and the war in Korea. Nor have wage rates, as distinct from earnings, actually risen quite as much as retail prices. The official index of retail prices was 129 in November, 1951, compared with 116 in November, 1950. There are also signs that the effects of devaluation on import prices are wearing off. Since July the monthly index of import prices has fallen.

But it would be much too optimistic to hope that an uneasy equilibrium has been reached between wages and prices. Already the higher wages for railway workers and coalminers have been reflected in increased freight charges, in higher monthly return fares, in—eventually—higher railway fares all round, and in higher prices for coal. Higher prices for coal increase the railways' costs, and higher freights increase the National Coal Board's costs. Higher prices for coal directly affect the price of gas and electricity, and together with increased transport charges enter into the costs of industry as a whole. The alarming prospect is that the country is beginning to enter a period of serious wage inflation superimposed on an inflation of prices.

Whether this is happening or not will not be apparent for some time. For the time being the big trade unions will doubtless be satisfied by the advances they have won. But food prices have already risen, and the Ministry of Food is being obliged to pay more for some of the food it buys abroad, while prices for home-produced food were increased at the end of November to take into account a £16m. wage award to farm workers. It is fairly certain that a new round of wage claims will, in the absence of a direct policy of restraint, begin in a few months' time.

Need to Reconcile Claims

Just then, however, the rearmament programme will be getting into its stride; labour for civilian production will be scarcer; and earnings, as distinct from wage rates, will be higher still. Next April the new Chancellor of the Exchequer will have to ask for an additional £700m. (compared with the present financial year) for the arms programme.

Once again, therefore, this year's Budget will be an exercise in reconciling claims on the country's resources. It can be assumed that there will be no reduction in the arms programme. Higher taxation, especially direct taxation, at a time when the country is already severely taxed, is likely to defeat its own ends. There are already signs that the rise in industrial output since the war is slowing down—that the Government can no longer rely on the national output expanding enough to satisfy the larger claims upon it. Heavier taxation, which damps incentive, is likely to slow down the expansion of resources even more.

An anti-inflationary policy remains therefore a question of cutting down the Government's own expenditure. The education service has already been warned. The Health Service, costing £400m. a year, can hardly escape.

DENTAL HAEMORRHAGES**FEES FOR TREATMENT**

As there has been some doubt about the correct fees a doctor may claim for treating dental haemorrhage, they are set out below.

The fee for arresting the bleeding is 15s., and if the doctor visits the patient's home he can in addition claim a fee of 7s. 6d., but both these fees are at present subject to an economy cut of 10%.

The fee for the arrest of haemorrhage is a fee per case and covers all treatment necessary in connexion with all the extractions carried out at one session. For example, if three teeth were extracted at one session, but the doctor treated the patient on two separate occasions, only one fee of 15s., less 10%, is payable. But if the two occasions when treatment was given were visits to the patient's home, then two fees of 7s. 6d., less 10%, may be claimed for the two separate home visits.

What most often happens is that a patient suffering from haemorrhage following tooth extraction calls on his doctor several times, and then only the one fee for treating the haemorrhage may be claimed.

CIVIL SERVICE DOCTORS**REPRESENTATIONS ON HOWITT REPORT**

The following agreed statement has been issued by the Treasury:

The Financial Secretary received a deputation [on January 3] from the Civil Service Medical Officers' Joint Committee representing the British Medical Association, the Institution of Professional Civil Servants, and the Ministry of Health Medical Staff Association. Representations were made about the remuneration of Civil Service medical officers with special reference to the recommendations of the Howitt Committee. The Financial Secretary undertook to report to the Chancellor of the Exchequer the views of the deputation, and he would reply to these as soon as possible.

MEETING AT WELSH HOUSE

Dr. Agnes Kelynack, Assistant Secretary, will speak at 5.30 p.m. on Thursday, January 24, at the Welsh House, 195, Newport Road, Cardiff. Her subject will be "The Present Position in the Public Health Field," and she will speak particularly on the award of the Industrial Court. Dr. H. R. Frederick, chairman of the Welsh Committee, will be in the chair.

Any member who wishes to attend and has not received an invitation is requested to communicate with Dr. S. J. Hadfield, at 195, Newport Road, Cardiff.

Nearly 100 preclinical and clinical students from many of the medical schools in Great Britain attended the fourth annual conference of the British Medical Students Association, held in Bristol on September 24-28. The conference was organized by the Bristol Medical School's Students' Society, which was greatly helped by the co-operation of the staffs of the University of Bristol and the Bristol Royal Hospitals. The delegates were welcomed by the Vice-Chancellor, Sir Philip Morris, and were received by the Lord Mayor of Bristol at the Mansion House. Lectures, demonstrations, and hospital ward rounds were arranged for both clinical and preclinical students. The social side of the conference was acknowledged to have been very successful, and the B.M.S.A. hopes that these annual conferences will continue to grow from strength to strength.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Entry to Partnership

SIR,—Every day that passes brings fresh evidence of the difficulty doctors not on the list of an executive council are experiencing in finding a way of entering general practice. The so-called evil of buying and selling practices has been replaced—in the absence of the promised health centres—by other real evils to which a practitioner is exposed even after appointment to a practice vacancy by the Medical Practices Committee—i.e., the inability to secure adequate housing accommodation in the practice area at a reasonable and economic figure, and the loss of units in the practice during the laborious advertising of the vacancy, selection of a suitable practitioner, and often the hearing of an appeal.

It is pathetic to find something in the region of 40 applications from a large percentage of excellent candidates for such vacancies, and, in the absence of any easy or obvious way of solving the difficulties set out, I feel that, apart from the obvious and very necessary step of raising the capita-tion fee, the trainee assistant scheme should be so adapted as to encourage and facilitate entry to partnership practice.

It has been my experience to have a succession of three trainee assistants in the partnership practice of which I am the senior partner. From the start my partners and I set out to facilitate the introduction of an assistant to the practice with the definite aim of offering a satisfactory trainee a practice share at the end of the training period. Our third trainee filled the bill, and, I am glad to say, is now a partner making up a firm of five. This step was taken gladly and with a full realization of the preliminary load on the partnership, but I feel that this load is discouraging other principals who may give consideration to the introduction of a trainee to the practice as a partner, and I feel that some adjustment here may be one way of facilitating entry to good general practice—keeping in mind the conditions under which permission to employ a trainee is granted.

When a trainee joins a partnership the principal loses the trainee salary previously paid by the executive council and has to carry the new partner in his early years without receiving any capital return, and without any possibility of the new partner receiving one of the much-abused basic salaries. The total cost may well be in the region of £2,000 in the first year. I suggest:

(1) that approval of the employment of a trainee assistant with a principal should be for a limited period only—e.g., three years of one year for each trainee employed, to give the principal a reasonable opportunity of ascertaining that the future partner is to be acceptable, and

(2) that a trainee who is legally introduced as a partner after his year's service should rank for a diminishing trainee grant over the first three to five years—e.g., two-thirds in the first year, half in the second, one-third in the third, as a suggestion.

In my opinion if this procedure is established it will facilitate the introduction of those seeking work as general practitioners to the best type of group practices without the necessity of facing the problems set out at the beginning of this letter, and do much to eliminate some of the difficulties that now exist, and will continue to exist, in the present economic state whatever the result of the long-awaited arbitration.—I am, etc.,

Bishop's Stortford, Herts.

R. P. GAMMIE.

Health Service Discipline

SIR,—Professional banishment from a town or county or a whole country is not entirely new. Among some African tribes banishment is still a punishment under tribal laws, though imposed only for very serious offences, as it

cuts the person off from his friends and seriously endangers his livelihood. Civil banishment in England persisted into the eighteenth century. It involved the loss of the society of one's fellows and of the protection of the law courts. By the N.H.S. Act of 1946 we were back again to the eighteenth century in that medical men were denied the protection of the law courts in matters arising out of the new health scheme. You will remember that our Socialist friend, Dr. H. B. Morgan, reasoned strongly with the then Minister of Health, as did others, on this point of elementary citizen justice without avail, the Minister giving the view quite frankly that the law courts would take power out of his hands.

Banishment in the old days was the punishment for crime or refusal to submit to a tribunal or its decrees. Outlawry has only been abolished in England comparatively recently by the Act of 1879, the last sentence being imposed in 1855. It was not, however, abolished in Scotland in the 1879 Act, which is amazing in a country with such liberal traditions.

This banishment of a doctor from his practice, livelihood, friends, old patients, and old associations is very serious. Wherever he seeks to start a new life his history will follow him from executive council to executive council throughout the land, and they may close all doors against him as an old offender. It is a dreadful business, and we seem not to be able to do anything about it. If such banishment had been imposed on a Glasgow docker the whole union would have paralysed the port and probably other ports as well. It seems a strange anomaly of our time that we depend on the less orderly, less reasonable, less responsible elements in our country for the preservation of our elementary rights while our orderliness, sense of responsibility, and professional virtues are getting us more and more tied up.—I am, etc.,

Shrewsbury.

ALBERT E. NICHOLLS.

SIR,—The timely letter from Dr. R. W. Cockshut (*Supplement*, December 29, 1951, p. 291) drawing attention to the serious issue raised by the action of the disciplinary tribunal at Glasgow will be welcomed by all who value freedom and who are concerned with the proper administration of justice. The question is, of course, not so much whether the tribunal acted within its rights, not whether the findings were correct, and not even whether the sentence imposed was just (and this last seems at least doubtful, especially in view of the result of the appeal to the Secretary of State), but whether such a body ought to be in a position to usurp functions which should be performed by the General Medical Council. It is, as Dr. Cockshut demonstrates so clearly, an intolerable situation that doctors should be "at the mercy of unwritten regulations."

Surely it should be possible for a man so accused and so severely dealt with to have the right of appeal to the G.M.C., which is after all not only the statutory body appointed by a definite Act of Parliament but is by its composition and experience far better fitted to deal with appeals than a Secretary of State. It is hardly necessary to point out that the G.M.C. would be automatically protected from having to deal with frivolous appeals owing to the power it possesses of being able to erase a name from the *Register*.—I am, etc.,

London, N.W.7.

A. H. MORLEY.

SIR,—The A.R.M. passed unanimously (*Supplement*, June 23, 1951, p. 271) a motion by Westminster and Holborn that:

This meeting views with grave disquiet the recent findings of certain medical service committees and the Tribunal. It demands that the procedure shall be overhauled and reiterates the principle that there must be a right of appeal to the courts.

Letters from Dr. W. A. S. Thom (*Supplement*, December 15, 1951, p. 266) and Dr. R. W. Cockshut (December 29, 1951, p. 291) prompt the question, What has happened to this resolution? In the Interim Report on Reform of the Health Service the vital question of right of appeal is not mentioned, and I find no reference to the matter in

your report of the S.R.M. (*Supplement*, December 22, 1951, p. 269), nor in your leading article (*Journal*, December 22, 1951, p. 1506). Dr. Sutherland told the meeting that his committee had picked out from the Acts the matters which they thought most important, and one would expect that a demand for the right of appeal would have been put in the forefront. Why delay action? In pressing for the withdrawal of this injustice the profession would have wide public support, for fundamental rights of the citizen are involved. I can visualize future Ministers, desirous of power, extending the principle to other professions and sections of the community. The position, if left as it is, will not stop at the doctors.—I am, etc.,

Sheffield.

HENRY BROWN.

** The Secretary of the Association writes: This resolution was referred to the G.M.S. Committee, which has appointed a representative subcommittee to review the whole of the disciplinary machinery. In the meantime all local medical committees have been asked for their views on the present arrangements and suggestions for their improvement.

Tracing Patients

SIR,—A lot has recently been written concerning the purging of G.P. lists. Recently my partner and I have been going through a list of patients to trace their addresses. In some the reason for inquiry has been stated to be that the house is demolished. I have, however, found this to be untrue. I also have found that no inquiries have in fact been made by the executive council, and I feel that their statement that this has been done must be taken with a large pinch of salt.

It seems that the efficiency of the council must be examined more fully: I find that notifications of acceptance since 1949 have not been followed by the record envelopes even now. It seems that one must demand from the council a full list of one's registrations, and then find out for which patients one has M.R.E.s. This would put a lot of work on to the council but would ensure that one was paid correctly.—I am, etc.,

London, W.6.

P. GORDON LEVER.

SIR,—As usual, practitioners are to blame for accepting conditions now existing. In my case in half an hour I "replaced" a hundred names on my list. Obviously no inquiry had been made by the executive council (the matron of a first-class nursing-home would certainly have replied to a letter). Of course the B.M.A. is not much help in defending the practitioner.—I am, etc.,

Glasgow, W.1.

J. E. KENNEDY.

SIR,—Is there any limit to the fierce indignities and abuses that are heaped upon general practitioners to-day? If one were to sit down and tabulate the unfair burdens that must be the daily lot of the practitioner the result would exceed in length the list of "Dos and Don'ts" presented to us when the National Health Service commenced.

The latest insulting demand is on the part of the various executive councils, who are requesting doctors to act as inquiry agents in order to prove the existence and whereabouts of patients named on lists; otherwise, we are informed, these names will be removed from the individual doctor's list.

While it is right and proper that redundancy should, as far as possible, be eliminated, why, oh why, should the onus of proof of whether these patients are still at risk lie with the hapless general practitioner? Why, indeed, should the busiest time of the year be chosen for the infliction of this task? It might take weeks of inquiry to elicit the current address of one person, let alone 75 persons who are listed for my attention. Is it expected that the general practitioner will, at his own expense, engage a team of private inquiry agents in order to trace these people?

Why did the B.M.A. condone this procedure? I take it that they did in fact agree with the Ministry of Health on this *modus operandi*, although as usual I did not see any

indication in the *Journal* that the opinion of the general practitioners had been sought in this matter.

In spite of cheap jokes made about general practitioners, they still remain a hard-working and conscientious body of men and women, who are reasonably well educated and trained to think logically. But it has always been a source of wonderment to me that they should allow themselves to be represented by leaders who are patently inarticulate on their behalf. Take, for instance, the vexed question of remuneration. While other sections of the community have in several instances managed to negotiate for two and sometimes three increments in their remuneration, our representatives have found it beyond their powers to settle with the Ministry the question of reasonable payment on entry into the National Health Service. This, mark you, after the latter has been in existence over three years.

If general practitioners were not so timid, frustrated, and tired, they would have sacked their representatives long ago and replaced them with men and women from their midst who would be prepared to do battle for their enslaved hosts. Until this is brought about, I am afraid that a new deal for general practitioners is about as far away as a peaceful settlement among the wrangling nations.—I am, etc.,

North Wingfield, near Chesterfield.

H. FIRMAN.

Payment of Dispensing Doctors

SIR,—As a rural practitioner I find myself wholly in agreement with Dr. J. Richards, of Newbury (*Supplement*, December 15, p. 267), when he pleads that our peculiar problems shall not be overlooked when it comes to implementing the various promises, broken and unbroken, of our recent Ministers of Health. But it is singularly unfortunate that he should choose for criticism the one item of service which at the moment of writing is fairly and reasonably paid. The dispensing payment by means of E.C. 10 forms completed, sorted, and sent quarterly to the Pricing Bureau is without doubt the fairest possible. The capitation method of payment shall be mentioned only to be condemned.

The doctor who has to dispense for his patients is bound to be put to extra trouble. Dr. Richards's suggestion will not save him much labour. The completion of Form E.C. 10 takes no longer in rural than in urban practice. The placing of the completed form in the appropriate box "S" or "A" cannot be called time-consuming; and, if a note is made at the time of writing of the number of forms and prescriptions on a separate piece of paper, the prescriptions can be bundled in hundreds with elastic bands as they accumulate, and the actual packing and dispatching four times a year is a negligible burden.

I would like to point out in passing that our friends the chemists have negotiated quite substantial increases for us recently, and the Pricing Bureau Superintendent is always ready to help with difficult problems like elastic hosiery.

If I may comment briefly on Dr. Richards's suggested alternative to the very excellent arrangements now in force, I should like to say that it is bureaucratic in conception, that it sacrifices the substance of independence to the shadow of salaried security, that it would almost certainly bring in less money, and that it appears to me to save neither time nor labour. The actual dispensing is the time-consuming part of the work, and if you cannot pay a dispenser or persuade your wife you will have to do it yourself whatever the method of remuneration.—I am, etc.,

Brailsford, Derbyshire.

J. J. HAMILTON.

SIR,—I am gratified to see that once again this unsatisfactory aspect of rural dispensing practice is receiving prominence. It has been brought up on innumerable occasions before and always it has proved an insoluble problem to the great administrative minds. Perhaps someone could explain to us why this should be. All we ask is payment for what we dispense, and for work done, without being put to a lot of time-wasting correspondence to collect our money.

The system of dispensing against Form E.C. 10 is too complicated and time-absorbing as well as being a losing

proposition on occasions. The dispensing capitation system is an easy arbitrary method of payment which does not keep pace with the rapid rise in the cost of drugs and dressings. The method of reclaiming payment for expensive preparations not on the schedule puts the doctor, the chemist, the executive council, and the Ministry of Health to endless trouble and correspondence.

To remove an expensive drug addict from the doctor's list is no cure, because the occasion arises when the patient has to be provided with drugs from the doctor's dispensary, for which payment is not forthcoming. I have on occasion invited such patients to purchase their supplies from the chemist direct and defray the cost from their own pockets, but this has invariably involved me in much correspondence and explanation with the executive council.

Dr. John Richards (*Supplement*, December 15, 1951, p. 267) suggests a method of dealing with the problem which I feel sure will be condemned out of hand owing to its sheer simplicity. A modification would be to adopt the system of dispensing against Form E.C. 10, and instead of receiving a dispensing fee the services of a dispenser-secretary could be provided or the expenses of one defrayed.

To pass from the sublime to the ridiculous: for real economy in prescribing I would advocate that all doctors in the N.H.S., hospital consultants included, be raised to the same responsible status as the rural dispensing doctor and be put on a dispensing capitation basis.—I am, etc.,

Harold, Beds.

R. STUART.

Compulsory Retirement in Hospital Service

SIR,—We have read with interest the correspondence concerning Mr. N. P. Jewell (*Supplement*, October 27, p. 188) and other consultants compulsorily retired. It is fair to put on record that the news of Mr. Jewell's compulsory retirement was heard with universal regret in this district and it was unanimously decided to sign a petition on his behalf. This received the signature of many general practitioners in this district, but was rejected by the regional hospital board and, after an appeal, by the Ministry of Health. Surely the time has come to recognize the fact that attaining the age of 65 years should not condemn a surgeon or physician to a life of idleness.

We feel that the cases of Mr. Jewell and his other equally eminent colleagues should be reconsidered in the light that a surgeon who is considered capable of private practice could equally be allowed to carry on practice as a general consultant under the National Health Service. It is a recognized fact that no surgeon over the age of 65 years would dream of carrying on operative surgery unless he himself felt capable of doing so.—We are, etc.,

M. E. WINTERS.

F. O'SULLIVAN.

Harrow, Middlesex.

Time to Instruct Counsel

SIR,—Since the bland announcement that it would take some months to instruct counsel in the case for the G.P. I have eagerly sought letters in the *Journal* from more authoritative and influential pens than mine protesting to high heaven. If our case is not virtually ready now, what on earth have our presumed leaders been doing since July, 1948, aye and before? Must we go on waiting, waiting, worried all the time by ever-mounting financial commitments which we are unable to meet?

Even were it granted that the capitation fee appointed by Mr. Aneurin Bevan at the beginning of the National Health Service was just and fair, it would need no elaborate preparation of a case to prove that in 1952 it will be utterly inadequate. Is it quite impossible to press *now* for an increase based on the manifest rise in the cost of living and on the increase in earnings of almost every other section of the community?

Over and over again one feels tempted to think that the man who is wholly dependent on his practice and whose practice is dependent on him is, in the nature of things, virtually debarred from the higher ranks of the B.M.A. This may in part account for the apparent fact that our represen-

tatives and "leaders" appear to be unaware that at this very moment many of us are torn and distracted by acute financial worries. We want help now.—I am, etc.,

Launceston, Cornwall.

DONALD M. O'CONNOR.

** The Secretary of the Association writes: The fact that it would take some little time to instruct counsel and our team of expert witnesses on the many facets of the profession's case was reported to the Annual Conference of Local Medical Committees and no exception was taken to the advice given by the G.M.S. Committee. Much of the evidence is based on the cost of living and the remuneration of comparable professions, and this must be submitted as from a current date.

Amenity Beds

SIR,—The medical profession will certainly agree with the sentence in Dr. David H. Patey's letter (*Supplement*, January 5, p. 6) in which he stated that, as doctors, we welcome an increase in the number of single-bedded ward units for those patients whose medical condition requires privacy. Such patients are not amenity-bed patients, but come into the category of what the Minister has called "medical-need patients"; and it is rightly laid down that a medical-need patient should always have the first call on any single-bed accommodation without charge.

Amenity beds are beds in single rooms or in small cubed wards which are charged at the inclusive rate of two guineas per week, and are not reserved for patients whose medical condition demands a separate room. They are helpful to elderly gentlefolk who appreciate quiet and privacy and whose reduced circumstances in the face of a rising cost of living make it impossible for them to afford a private room. Unfortunately, the demand for these beds often comes from social snobs who do not want to be in wards with their fellow-beings, but who pay a sum which is scarcely sufficient to cover the cost of their board and lodging. What is also unfair is that such a large number of amenity beds have been established in the private blocks of hospitals solely by a change of nomenclature, so that patients in them get the same advantages and treatment as those given to patients in identical beds who have to pay 13-23 guineas a week, together with charges for drugs and medical attention: nearly 2,000 private beds have been converted into amenity beds.

Surely the remedy is to reduce the cost of pay-beds to a level which makes them an economic possibility for those who have saved for a "rainy day," so that they may have a little extra comfort when illness befalls them. They were originally established for this purpose, and only political considerations have insisted on the conversion of fee-paying beds into amenity beds, while forcing up the cost of the fee-paying bed. The ultimate aim is clearly to abolish private practice and establish a State monopoly.—I am, etc.,

London, W.1.

E. C. WARNER.

POINTS FROM LETTERS

Tracing Patients

Dr. I. LIBMAN (Heywood, Lancs) writes: I am amazed that the British Medical Association has given its consent to the local executive councils with regard to tracing of patients. This decision will cause great inconvenience to the practitioner and it will entail many extra hours of clerical work on top of our heavy winter rush of urgent cases which keep us busy for twenty-four hours each day. . . . The burden of the National Health Service is being borne solely by the practitioners, and they are doing a grand job in spite of the lack of assistance from the Government and the executive council and are meeting the rush of patients in a valiant manner. Most practitioners with whom I have been in contact are completely against this decision with regard to tracing patients. If all practitioners are hostile to the procedure, then it is up to the B.M.A. to inform the executive council of their decision to withhold their consent. . . .

Association Notices

AREA OF PORTSMOUTH AND SOUTHAMPTON DIVISIONS

Notice is hereby given that the Council has transferred the civil parishes of Sarisbury, Hook with Warsash, and Locks Heath from the area of the Portsmouth Division to that of the Southampton Division.

A. MACRAE,
Secretary.

Diary of Central Meetings

JANUARY

- 15 Tues. Staff Side Committee B, 11 a.m.
- 15 Tues. Finance Inquiry Committee, 11.15 a.m.
- 15 Tues. Finance Committee, to follow Finance Inquiry Committee.
- 15 Tues. Whitley Committee B (at 1, Richmond Terrace, Whitehall, S.W.), 2.30 p.m.
- 16 Wed. General Practice Review Committee, 11 a.m.
- 17 Thurs. Publishing Subcommittee, 10.30 a.m.
- 17 Thurs. General Medical Services Committee, 11 a.m.
- 18 Fri. Consulting Pathologists Group Committee, 2 p.m.
- 22 Tues. Staff Side of Committee C (at 1, Richmond Terrace, Whitehall, S.W.), 10 a.m.
- 22 Tues. Whitley Committee C (at 1, Richmond Terrace, Whitehall, S.W.), 12 noon.
- 22 Tues. "Dual Appointments" Conference (at 1, Richmond Terrace, Whitehall, S.W.), 3.30 p.m.
- 23 Wed. Council, 10 a.m.
- 24 Thurs. Subcommittee re Arbitration on Remuneration of General Practitioners, General Medical Services Committee, 10.30 a.m.
- 24 Thurs. Registrars Group Executive Committee, 2 p.m.
- 25 Fri. Venereologists Group Committee, 2.30 p.m.

FEBRUARY

- 1 Fri. Committee re Fees for Part-time Work under Local Authorities, 2 p.m.

Branch and Division Meetings to be Held

BARNSTAPLE DIVISION.—At Imperial Hotel, Barnstaple, Thursday, January 17, 7.15 for 7.30 p.m., dinner with North Devon members of the legal profession, followed by address by Dr. Robert Forbes: "Legal Hazards in Medical Practice."

BIRMINGHAM DIVISION.—At Birmingham Medical Institute, 154, Great Charles Street, Birmingham, Tuesday, January 15, clinical meeting by Miss Dorothy M. Shotton.

BURTON-ON-TRENT DIVISION.—At General Infirmary, Burton. Tuesday, January 15, 8 p.m., clinical meeting. A series of cases will be shown illustrating hypertension.

CITY DIVISION.—At Metropolitan Hospital, Kingsland Road, London, E., Tuesday, January 15, 8.30 p.m., meeting.

EAST KENT DIVISION.—At Winter Gardens, Margate, Friday, January 18, 9 p.m. to 2 a.m., annual supper and ball in aid of Royal Medical Benevolent Fund.

GREENWICH AND DEPTFORD DIVISION.—At Miller General Hospital, Greenwich High Road, London, S.E., Wednesday, January 16, 8.30 p.m., lecture by Dr. D. D. Towle: "Medical Aspects of Atomic Warfare." Illustrated by a film. Members of Lewisham and Woolwich Divisions and others interested are invited.

LAMBETH AND SOUTHWARK DIVISION.—At Lambeth Hospital, Brook Drive, London, S.E., Tuesday, January 15, 8.15 p.m., motion picture with sound: "Radiography of the Vertebrae."

LINCOLN DIVISION.—Thursday, January 17, meeting in association with Lincolnshire Medical Society. (1) At Saracen's Head Hotel, 7.15 for 7.45 p.m., dinner; (2) at Lindsey County Council Offices, 8.45 p.m., B.M.A. Lecture by Dr. G. W. M. Findlay: "Antibiotics."

MID-ESSEX DIVISION.—At Reception Hut, St. John's Hospital (upper entrance), Wood Street, Chelmsford, Sunday, January 20, clinical meeting, 10.15 a.m., talk by Mr. Anthony Pearson: "Cervix Uteri in Obstetrics"; 11.30 a.m., discussion on everyday obstetric problems.

SOUTHAMPTON DIVISION.—At Nurses' Lecture Hut, Royal Southampton Hospital, Wednesday, January 16, 8 for 8.30 p.m., general meeting. Address by Dr. W. S. C. Copeman: "Cortisone, A.C.T.H., and the Rheumatic Diseases."

SUNDERLAND DIVISION.—At Royal Infirmary, Sunderland, Friday, January 18, 8 p.m., address by Mr. John Bruce: "Pain in the Right Iliac Fossa."

WOOLWICH DIVISION.—At Woolwich Memorial Hospital, Shooters Hill, London, S.E., Tuesday, January 15, 8.30 p.m., lecture by Dr. Francis Camps: "The Modern Approach of the Forensic Pathologist to a Case of Murder by Violence." Illustrated by lantern slides.

THE BRITISH PHARMACEUTICAL CODEX 1949

An authoritative book of reference prepared with the assistance of eight committees of experts representing all branches of medical and pharmaceutical knowledge and experience, and working under the general direction of the Council of the Pharmaceutical Society of Great Britain.

The book prescribes standards for and gives comprehensive details of the action, uses, and methods of administration of over 1000 substances used in medicine—vegetable and animal drugs, synthetic chemicals, antibiotics, biological products. Other sections provide information on blood products, surgical sutures, ligatures and dressings.

There are nearly 900 formulæ of tested pharmaceutical preparations and twelve appendices.

Pp. xxv + 1563 . . Price 63s. (postage 1s.)

SHARP as a TOLEDO SWORD

The swords of Toledo were long famed as the sharpest in Europe. They were hand made by craftsmen. VIM needles are also famed for their sharpness. Skilful grinding by craftsmen produces VIM's incomparable razor-keen points and cutting edges. Made from Firth-Brearley stainless steel, uniformly tempered, with accurately tapered mounts and individually tested. . . . The perfect instrument for safe, pain-free injections.

Always use

A new preparation of

Aspirin for Children

A SAFE AND ACCURATE DOSE OF ASPIRIN—There is little fear of an anxious mother giving too large a dose of Angiers Junior Aspirin for Children. Each tablet contains $1\frac{1}{4}$ grains of Aspirin.

IN AN EASY TO TAKE TABLET—The pleasant orange flavour and sweetening in this small pink tablet makes Angiers Junior Aspirin acceptable to children even if sucked or chewed.

WITH A SAFEGUARD AGAINST GASTRIC IRRITATION—The combination of di-calcium phosphate with the aspirin guards against any irritation caused by the acid effect of the aspirin.

Acid. Acetylsalicylic. 1.25 grains. Di-
Calcium Phosphate 1.50 grains, sweetening
and orange flavouring to taste.

Bottles of 50 tablets 1/6

ANGIERS JUNIOR ASPIRIN for children

EPHAZONE tablets

*Rational, symptomatic
treatment in
Asthma & Bronchitis*

Each tablet contains Ephedrine, the important anti-spasmodic for bronchial spasm, Theobromine, for its relaxing effect on the bronchial muscle and for stimulation of the coronary circulation, Phenazone, for its soothing effect on the higher centres, and Calcium gluconate, a readily absorbable calcium salt, for diminishing capillary permeability and checking the secretion of mucus.

These active ingredients with complementary effects in bronchial asthma are presented in the following proportions in the 'EPHAZONE' Tablet:

Ephedrine hydrochloride	- - -	$\frac{1}{4}$ grain
Theobromine	- - -	$\frac{1}{2}$ grain
Phenazone	- - -	1 grain
Calcium gluconate	- - -	$\frac{1}{2}$ grain

This preparation is sanctioned for prescription under N.H.S. Please write for samples and descriptive leaflet.

The good
that lives on

There are so many ways of hurting a child. Lack of love and companionship, confinement, for whole days at a time, alone in a bare room — these are examples of the not-so-obvious forms of cruelty. And so, if you want to make a bequest to a really good cause, you could not find a better one than the NATIONAL SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN. Its business is to protect and it only prosecutes when help and advice have failed.

when making your will, please remember the

A FINE RELIEVING AGENT WITH A FINE RECORD

The importance of protein during pregnancy and the nursing period

CLINICAL observation shows that the increased protein anabolism during the latter part of pregnancy, and particularly during the nursing period, requires more protein than was at first considered necessary. Adequate protein is, therefore, desirable to ensure the ample supply of breast milk.

The inclusion of high-grade protein foods in the diet of pregnant women is now a standard practice. In cases where there is loss of appetite

or a general feeling of exhaustion, the diet can be effectively supplemented by protein foods in a form which is easy to assimilate.

Brand's Essence is a first-class protein of animal origin. Being partly hydrolysed, it is capable of easy ingestion, digestion and absorption. It is extremely palatable, and may be taken either as a jelly or as a liquid. It helps to support convalescence and assists in restoring a positive nitrogen balance.

Advantages of the Daimler Limousine Ambulance Service

It is often necessary for patients to travel by road. A normal car is usually too fatiguing, yet in many cases the patient wishes to avoid travelling in a public ambulance.

This need is met by engaging a Private Limousine Ambulance from Daimler Hire Ltd. The Ambulance has the appearance of a large private limousine and does not attract attention from the public.

A fully trained attendant accompanies each driver and both are competent stretcher bearers. Each Limousine Ambulance is specially designed for the purpose and is equipped with a swivelling bed, folding carrying chairs, canvas carrying slings and sick-room cabinet. Air beds are available if required. Two comfortable chair-seats are provided for friends. Adequate heating and ventilating is automatically assured.

★ A booklet giving full details of this service is available on request. Please write or telephone :—

JAEGER

Jaeger body-belts are made of pure wool, for these reasons. Wool keeps its wearer cool in summer, warm in winter. Wool disposes quickly of perspiration, retaining body warmth. Wool, being porous, allows both the escape of exhalations from the skin, and the access of pure air to the skin. Jaeger body-belts sit well, stay in position, and give support without pressure. They are available in all sizes.

JAEGER HOUSE, 204-206 REGENT STREET, W.1

It has been noted that the patient on an Intalok mattress enjoys a greater degree of peaceful rest and relaxation.

The reason is clearly shown in this illustration.

The background photograph shows a top-view of a section of the mattress. It consists of a mass of fine gauge springs loosely interlinked throughout the whole length and breadth. Surface coils take the first pressure, and as weight increases, more and more springs share the load.

The diagram shows how the mattress reacts when the patient is placed upon it. The springs conform exactly to the shape of the body. Where pressure is great there is deep compression—yet, as the springs are interlinked, there is no excessive resistance—no flattening of fleshy parts, to cause soreness or fatigue. The patient is comfortably and naturally supported.

Here are other good reasons why hospital authorities are in favour of Intalok mattresses:

- 1 The mattresses can be stoved; in fact they gain by stoving.
 - 2 All metal parts are rustless, can be sterilized repeatedly.
 - 3 Intalok mattresses have no tufts or piping to collect dust and germs.
 - 4 The ticking is easily removable for laundering.
 - 5 Existing hair mattresses can be converted to Intalok—the good hair being retained. This cuts costs.
 - 6 Every Intalok springing unit is guaranteed for 10 years.
- Write today for illustrated leaflet and prices.

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★*SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.*

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held, £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not registrars and who have less responsibility than other hospital officers of non-consulant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

(5536)

Psychiatry—contd.

BIRMINGHAM, UNITED, HOSPITALS
REGISTRAR to the Psychiatric Department
 Applications are invited for this appointment, Senior Registrar Grade. Candidates must be medical practitioners, registered for not less than two years, and must hold the D.P.M. (or Part I). The post offers good facilities for training. The psychiatric department is an integral part of the departments of neurology, neurosurgery and psychiatry of the teaching hospital and of the University. The duties will include work in both the in-patient and out-patient departments of the hospital. Applications should be submitted on a special form which will be forwarded on request to the undersigned, from whom all further information may be obtained.—G. A. Phalp, Secretary, United Birmingham Hospitals, Queen Elizabeth Hospital, Birmingham, 15. (5742)

CAMBRIDGE (near), FULBOURN MENTAL HOSPITAL
East Anglian Regional Hospital Board
REGISTRAR in Psychiatry

There are 750 beds in the hospital, which includes a very active early treatment unit. It affords facilities for teaching and research to the department of experimental psychology of Cambridge University and runs out-patient clinics in general hospitals. The appointment will be for one year, renewable for a second year. Applications, stating age, qualifications and details of present and previous appointments, together with the names of three referees, should reach the undersigned not later than January 21, 1952. Candidates are invited to visit the hospital by direct arrangement with the Medical Superintendent.—K. V. F. Morton, Sec., 117, Chesterton Road, Cambridge. (5309)

DUNDEE (by), BAIDOVAN INSTITUTION
 (400 beds)
Eastern Regional Hospital Board (Scotland)
 Applications are invited for the post of
SENIOR REGISTRAR

In the Regional Establishment for Mental Deficiency. Authorized training post. Salary and conditions of service in accordance with national agreement. Further particulars and forms of application may be had from the Secretary to the Board, 430, Blackness Road, Dundee, with whom applications must be lodged not later than January 26, 1952. (5940)

IPSWICH, ST. CLEMENT'S MENTAL HOSPITAL
East Anglian Regional Hospital Board
REGISTRAR in Psychiatry

The hospital, which has 400 beds, is situated in the town and does a large volume of out-patient work both on the premises and in the general hospitals. The appointment includes the opportunity to make regular weekly attendances at a modern child guidance clinic under the direction of a full-time consultant. The appointment will be for one year, renewable for a second year. Applications, stating age, qualifications and details of present and previous appointments, together with the names of three referees, should reach the undersigned not later than January 21, 1952. Candidates are invited to visit the hospital by direct arrangement with the Medical Superintendent.—K. V. F. Morton, Secretary, 117, Chesterton Road, Cambridge. (5310)

MAIDSTONE, KENT, OAKWOOD HOSPITAL
South-East Metropolitan Regional Hospital Board
 Applications are invited to fill a vacancy for a
WHOLE-TIME REGISTRAR in Psychiatry
 Previous experience in general medicine is desirable. The appointment will be for one year in first instance and in accordance with the terms and conditions of service of hospital medical and dental staff (England and Wales). The post will include opportunities for gaining further experience in a wide range of psychiatry. Applications, giving particulars of age, qualifications and experience, with relevant dates, together with the names and addresses of three referees, should be sent to the Secretary, Registrars Committee, South-East Metropolitan Regional Hospital Board, 11, Portland Place, London, W.1, not later than January 25, 1952. Candidates will be interviewed in London on February 11, 1952. (5691)

WOKING, BROOKWOOD HOSPITAL
 (1,600 beds)
South-West Metropolitan Regional Hospital Board
Brookwood Hospital Management Committee
Knap Hill, Woking, Surrey
 Applications are invited for the post of
PSYCHIATRIC REGISTRAR

Candidates, who should be single, must have held house appointments in a general hospital, but no previous psychiatric experience is necessary. The hospital staffs several out-patient clinics and carries out all modern methods of treatment. There are facilities for attending courses of instruction in London for the D.P.M. The appointment is resident and the salary and conditions of service are in accordance with the Ministry of Health regulations. Candidates may visit the hospital by arrangement with the Physician Superintendent. Application forms are obtainable from the Secretary, Brookwood Hospital, Knap Hill, Woking, Surrey, to whom they should be returned, duly completed, not later than fourteen days after the appearance of this advertisement. (5803)

SEDGEFIELD, WINTERTON MENTAL HOSPITAL

Newcastle Regional Hospital Board
WHOLE-TIME REGISTRAR (Resident)
 Salary £775 to £890. Appointment for one year, which may be renewed for a further year. Arrangements can be made for the person appointed to take the necessary course of study for the University of Durham diploma in psychological medicine. Appointment subject to national terms and conditions of service, and the National Health Service (Superannuation) Regulations, 1950. Applications together with one/three referees and/or one/three testimonials, should be sent to the Regional Psychiatrist, Blythwood South, Osborne Road, Newcastle-upon-Tyne, 2, within fourteen days. (5715)

WALLINGFORD (near), BERKS, FAIR MILE (MENTAL) HOSPITAL, and ancillary premises
Oxford Regional Hospital Board
 Applications are invited for the whole-time post of
REGISTRAR in Psychiatry

The appointment will be for one year and eligible for extension to a second year. An unfurnished house is available. Applications, on forms obtainable from the Secretary, Registrar Committee, 43, Banbury Road, Oxford, should reach him by February 1. (5692)

BIRMINGHAM, RUBY HILL HOSPITAL
 (950 beds)
No. 6 Group (Mental B) Hospital Management Committee

Applications are invited for the post of
JUNIOR HOSPITAL MEDICAL OFFICER
 (Male or female) (Resident or non-resident)
 Out-patient clinic held at Selly Oak Hospital, Birmingham. Valuable experience provided in the diagnosis and treatment of all forms of neurosis and psychosis. Previous postgraduate psychiatric experience not essential. Appointment in accordance with the National Health Service terms and conditions of service. Applications, stating full name, age, nationality, qualifications and experience, and providing the names of three referees, to be sent within fourteen days of this advertisement to the Secretary, Offices of the Group H.M.C., Rubery Hill Hospital, Birmingham. (5693)

CANTERBURY (near), ST. AUGUSTINE'S HOSPITAL, Chatham

Applications are invited by the Management Committee of this hospital for mental and nervous disorders, from registered practitioners, male or female, for the following posts:

JUNIOR HOSPITAL MEDICAL OFFICERS
 (Two posts). Salary £700 per annum by £50 to £1,000 per annum.

SENIOR HOUSE OFFICERS (Two posts)
 for tenure of one year. Salary £670 per annum. A house is available on the hospital estate, for which a rental will be charged. Unmarried accommodation is also available in the hospital, for which a charge of £150 per annum will be made. Apply to the Medical Superintendent, stating nationality, age, sex, qualifications and experience, with the names of three referees, within fourteen days of this advertisement. (5743)

EPSOM, SURREY, THE MANOR (1,332 beds)
 Applications are invited for the post of
JUNIOR HOSPITAL MEDICAL OFFICER or SENIOR HOUSE OFFICER

The hospital caters for patients of all ages and both sexes certified under the Mental Deficiency Act and provides excellent opportunities for research in high grade mental defectiveness associated with delinquency and behaviour disorders. It is a recognized institution for the purposes of the D.P.M. examination. Special departments include school and psychological units, and an extensive employment and licensing system is operated from The Manor and its two hostels. Applications, stating name, date and place of birth, nationality, details of education, professional qualifications, and present and previous appointments, with names and addresses of three referees, should reach the Physician Superintendent, The Manor, Epsom, Surrey, not later than fourteen days after the publication of this advertisement. (5655)

WELLS, SOMERSET, MENDIP HOSPITAL
 (920 beds)

Applications are invited for the appointment of

PUBLIC HEALTH

(See Important Notice page 25)

MIDDLESEX COUNTY COUNCIL

County Health Department

ASSISTANT MEDICAL OFFICER (Whole-time)

Required initially in Area 3 (Hornsey and Tottenham). Duties include supervision of health of young children attending infant welfare clinics, toddlers clinics and day nurseries, with routine medical inspections at schools and attendance at clinics for school children. Should possess D.P.H. or equivalent qualification. Salary £850 by £50 to £1,150 per annum inclusive. Established. Subject to medical assessment and prescribed conditions. Applications (no forms), stating age, qualifications, experience, two referees, to Area Medical Officer, Local County Offices, Somerset Road, Tottenham, N.17, by January 26 (quoting K.310 B.M.J.). Censoring disqualifies.—C. W. Radcliffe, Clerk of the County Council. (5868)

Public Health—contd.**BOLTON, COUNTY BOROUGH OF**
Three vacancies exist for
ASSISTANT MEDICAL OFFICERS OF HEALTH
AND ASSISTANT SCHOOL MEDICAL
OFFICERS OF HEALTH

and applications are invited from suitably qualified registered medical practitioners for such vacancies. The duties will be mainly in connection with the Maternity and Child Welfare Service and the School Health Service, but the persons appointed will be expected to carry out such duties as may be allotted to them by the Medical Officer of Health. The possession of a D.P.H. or a D.C.H. is desirable, but not essential. The salary will be on the appropriate step of the scale, £850 rising by annual increments of £50 to £1,150 per annum, according to experience and qualifications. The appointments will be subject to the provisions of the Local Government Superannuation Acts, and the successful candidates will be required to pass a medical examination. Appointments will be terminable by one month's notice on either side. There are no forms of application, but further particulars can be obtained from the Medical Officer of Health, Civic Centre, Bolton. Applications, giving full particulars of age, qualifications, and experience, and the names and addresses of three referees, should be forwarded to the undersigned not later than January 24, 1952.—Phillip S. Rennison, Town Clerk, Town Hall, Bolton. (5521)

CAERNARVONSHIRE COUNTY COUNCIL
ASSISTANT COUNTY AND SCHOOL MEDICAL
OFFICER

Applications are invited for the above post from those possessing the Diploma or Certificate in Public Health. The salary scale will be £850 by £50 to £1,150, and the commencing salary on this scale may be determined by the length of service in a similar post. Opportunities are available for gaining experience in public health administration. Travelling and subsistence allowances will be paid in accordance with national scales. A knowledge of Welsh is desirable. Further information may be obtained from the County Medical Officer of Health. Applications, giving complete particulars of training and experience, together with copies of two recent testimonials and the names of two referees, should be sent to the undersigned by not later than January 31, 1952.—Gwilym T. Jones, Clerk of the County Council, County Offices, Caernarvon. (5866)

NORTHUMBERLAND COUNTY COUNCIL
School Health Service

Applications are invited from registered medical practitioners for the post of

ASSISTANT SCHOOL MEDICAL OFFICER
(Male or female)

Preference will be given to candidates who have experience in the diseases of children, and to those who have been approved by the Minister of Education for the purpose of the ascertainment of educationally subnormal pupils. The salary will be at the rate of £850 per annum, rising by annual increments of £50 to a maximum of £1,150 per annum. Previous experience may be taken into consideration in determining the commencing salary. Travelling expenses and subsistence allowances, in accordance with the Council's scale, will be paid. The appointment is subject to the provisions of the Local Government Superannuation Act, 1937, as amended by the National Health Service (Superannuation) Regulations, and the successful candidate will be required to pass a medical examination. Forms of application, which may be obtained from Dr. J. B. Tilley, School Medical Officer, County Hall, Newcastle-upon-Tyne, 1, should be returned not later than January 26, 1952.—E. P. Harvey, Clerk of the Council, County Hall, Newcastle-upon-Tyne, 1. (5402)

NOTTINGHAM, CITY OF
Health Department

Applications are invited from qualified medical practitioners for the post of

ASSISTANT MEDICAL OFFICER OF HEALTH

The duties will be chiefly in connexion with maternity and child welfare, together with any other duties allocated by the Medical Officer of Health. Preference will be given to candidates possessing higher qualifications and the salary attached to the appointment will be £850 by £50 to £1,150 per annum. The post will be subject to three months' notice on either side at any time. The successful candidate will be required to pass a medical examination under the provisions of the National Health Service (Superannuation) Regulations or the Local Government Superannuation Act, 1937. Conditions of appointment and forms of application may be obtained from the undersigned to whom they must be returned, together with the names of two persons to whom reference may be made, not later than January 26, 1952.—T. J. Owen, Town Clerk, The Guildhall, Nottingham. (5671)

GLAMORGAN EDUCATION AUTHORITY
Rhondda Urban District Council
Committee for Education

Applications are invited from registered medical practitioners for appointment as

MALE ASSISTANT MEDICAL OFFICER

under the supervision of the District School Medical Officer at a salary of £850 per annum, rising by annual increments of £50 to £1,150 per annum. Preference will be given to candidates holding the D.P.H. or D.C.H. and experience in paediatrics will be an advantage. The successful candidate, if in need of housing accommodation and not already a resident of the Rhondda Urban Area, may be offered the tenancy of a Council house. Forms of application and conditions of appointment may be obtained from the District School Medical Officer, Tydfil House, Pentre, Rhondda, by whom completed applications should be received as soon as possible.—D. J. Jones, Clerk of the Council. (5867)

SOMERSET COUNTY COUNCIL
ASSISTANT COUNTY MEDICAL OFFICER OF
HEALTH

Applications (men or women) are invited for the above appointment. The salary is £850, rising by £50 to £1,150 per annum, but in fixing the commencing salary the Council will have regard to previous experience. Possession of the D.P.H. or D.C.H. would be an advantage. The duties will be mainly concerned with the services of school medical inspection and maternity and child welfare. Possession of a motor car is essential. Travelling allowance will be paid in accordance with the county scale. The post is superannuable and subject to a satisfactory medical examination. Applications should be made forthwith, on forms to be obtained from the undersigned.—J. F. Davidson, County Medical Officer of Health, County Hall, Taunton. (5670)

STOCKTON-ON-TEES, BOROUGH OF

Applications are invited from duly qualified medical practitioners for the position of

ASSISTANT MEDICAL OFFICER OF HEALTH
AND ASSISTANT SCHOOL MEDICAL OFFICER

The salary will be at the rate of £850 per annum, rising by annual increments of £50 to £1,150 per annum. The duties of the appointment will be principally of a clinical nature and will concern the school health service and the general work of the department. Preference will be given to candidates who hold a Diploma in Public Health or a Diploma in Child Health. The person appointed will not be allowed to engage in private practice and the appointment will be subject to two months' notice. Applications, giving particulars of age, qualifications, experience and present and previous appointments, together with the names of two persons to whom reference may be made, endorsed "Assistant Medical Officer of Health," must be received by the undersigned not later than January 20, 1952.—John B. Haworth, Town Clerk, Barclays Bank Chambers, Stockton-on-Tees. (5572)

SWINDON, BOROUGH OF
DEPUTY MEDICAL OFFICER OF HEALTH
AND SCHOOL MEDICAL OFFICER

Applications are invited from duly qualified medical practitioners holding a Diploma in Public Health or similar qualification for the appointment of Deputy to the Medical Officer of Health and Borough School Medical Officer who is also Area Medical Officer under the Wiltshire County Council. The salary and conditions of service will be in accordance with the recent award of the Industrial Court. The present salary is at the rate of £1,034 per annum, rising by four increments of £50 to a maximum of £1,234 per annum. Assistance will be given in the provision of housing accommodation if required. Forms of application and further particulars of the post may be obtained from the undersigned with whom applications should be lodged not later than Saturday, January 19, 1952.—D. Murray John, Town Clerk, Civic Offices, Swindon. (5256)

INDUSTRIAL APPOINTMENTS**"MEDICAL ADVISER ON PUBLICITY" . . .**

The advertisers (Box No. 1924, B.M.J., Dec. 29, 1951), wish to thank the many applicants for the post and to announce that after careful consideration to each application an appointment has now been made.

NORTH WESTERN GAS BOARD.—APPLICATIONS are invited for the new post of **Chief Medical Officer** to the Board at a commencing salary of £2,300 per annum. Applicants should have experience of industrial medicine and should possess a higher qualification. The successful candidate may be required to pass a medical examination and to subscribe to such superannuation scheme as the Board may adopt. Detailed applications, including the names of three referees, should reach the Secretary, North Western Gas Board, 60, Whitworth Street, Manchester, 1, by January 21, 1952. A brief outline of the scope of this post may be obtained on application to the above address. (5767)

OVERSEAS**ALBANY HOSPITAL, Albany, N.Y.**

CAMEROONS DEVELOPMENT CORPORATION
Cameroons under British Trusteeship, West Africa
Vacancies exist for**MEDICAL OFFICERS**

In the service of the Cameroons Development Corporation, established by statute for the development of certain plantation areas in the British Cameroons. The appointment in the first instance will be for one tour of 12 to 24 months, with probability of renewal if service satisfactory. Candidates should have a good experience of general medical and health work, and preference will be given to those who either possess a diploma in tropical medicine, or have had tropical experience. The work chiefly consists of general medical and health supervision of all personnel in large plantations, but offers opportunity for surgery. First-class passages are provided to and from the Cameroons for officers and their wives, together with free furnished accommodation during residence in the Cameroons. A reasonable amount of free lighting and fuel is also provided, and necessary transport. An outfit allowance of £80 is payable on first appointment. The salary is at the rate of £1,310 rising by increments to £1,710 per annum over a period of 10 years; initial salary according to experience. Children's allowances are paid up to a maximum of two, but children's passages are not paid. Officers of the Corporation are required to contribute 10% of their salary to the Provident Fund, the Corporation contributing a like amount. Applications, giving full particulars in regard to qualifications and experience, together with copies of testimonials, all in triplicate, should be sent to the Corporation's London agents: Rubber & Mining Agencies, Ltd., 52, Leadenhall Street, London, E.C.3. Candidates should have performed their National Service. (5919)

DEPARTMENT OF HEALTH, NEWFOUNDLAND

The Newfoundland Department of Health requires internes for the 450-bed General Hospital situated in the capital city of St. John's. This hospital is approved for internship by the Canadian Medical Association, and the rotating interne arrangement guarantees services in General Surgery, General Medicine, and in at least two of Orthopaedics, Paediatrics, Radiology, and Ear, Eye, Nose, and Throat. There is also a one month affiliation in Obstetrics.

These posts carry a salary of \$1,800.00 per annum (Canadian funds) together with full maintenance at the institution. Full cost of transportation to Newfoundland is paid by the Department of Health and the cost of return transportation is paid at the end of one year's satisfactory service. Interested applicants should apply to the Medical Superintendent, General Hospital, St. John's, Newfoundland, Canada.

Overseas—contd.

VANCOUVER GENERAL HOSPITAL
 Vancouver, Canada
ASSISTANT RESIDENT AND SENIOR RESIDENT,
 in Paediatrics

Required for one year commencing July 1, 1952. Honorarium:—Assistant \$80, Senior Resident \$150 monthly, both plus full maintenance.

Required for one year, commencing July 1, 1952, or sooner. Honorarium:—Assistant \$80, Associate \$125, both plus full maintenance.

Address inquiries to Secretary, Interne Committee, Vancouver General Hospital, Vancouver, Canada. (5781)

HIS MAJESTY'S COLONIAL SERVICE, Malaya
 Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom, with one or more years' experience after qualification, are required for appointment as **MEDICAL OFFICERS AND MEDICAL OFFICERS OF HEALTH**

for general medical and health duties. A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan medical service. Appointment is available (a) on probation for permanent establishment, (b) on employment from the National Health Service, and (c) on short term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale 1952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g. F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malayan salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their Colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e. those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 77215/242751) (5187)

UNIVERSITY APPOINTMENTS

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL
 Department of Obstetrics and Gynaecology

 Physics as Applied to Radiotherapy W. J. MEEDITH and Physics Staff
 Radiobiology and Pathology DR. E. PATERSON, DR. W. M. DALE, and DR. H. RUSSELL

There are some Junior appointments available at the Christie Hospital under the National Health Service for which successful candidates would be eligible to apply. Special consideration will be given to candidates possessing a higher qualification in medicine and surgery (for whom posts as Registrars may be available). Further information may be obtained from the Director, Holt Radium Institute, Wilmslow Road, Manchester, 20. Applications must be sent to the Dean of the Medical School, University of Manchester, and all applicants will be required to attend for interview. (5765)

APPLICANTS ARE ADVISED NOT TO SEND original testimonials when replying to advertisements. Copies will answer the purpose quite as well, and in the event of their being lost or mislaid no inconvenience will ensue.

EDUCATIONAL

F.R.C.S. POSTAL COURSES FOR PRIMARY AND FINAL EDIN. and L.N.G. RECIPROCAL EXAMS. Full details also of Private Tuition.—H. C. Orrin, F.R.C.S., Surgeons' Hall, Edinburgh.

D.OBSTET.R.C.O.G.: COURSE OF LECTURES for March examination commencing shortly. London.—Box 2011, B.M.J.

PRIMARY F.R.C.S., PHYSIOLOGY AND Pathology. Short course, February to April, in London by experienced teachers. C.N.S., Respiration, Circulation, General Pathology. Telephone: PRI 8266.—Box 152, B.M.J.

D.P.M., M.D., THESES. SPECIAL PERSONAL Postal Tuition by late D.P.M. Examiner. Modern courses. Many successes. Expert aid for all theses by F.R.C.P. A complete thesis service.—Box 101, B.M.J.

M.B. AND CONJOINT. REVISION COURSE in Physiology in London by experienced teacher, late afternoons. Tel.: PRI 8266.—Box 153, B.M.J.

GENERAL SURGERY (F.R.C.S.) WEEK-END: All day Saturday and Sunday, January 26 and 27. Queen Mary's Hospital for the East End, Stratford. Apply Fellowship of Postgraduate Medicine, 60, Portland Place, London, W.1. Langham 4266.

GENERAL MEDICINE (M.R.C.P.): FEBRUARY 4 to March 15, 5 to 8.30 p.m. daily. Lectures, clinical cases, pathology, X-rays. Whittington Hospital (Archway Wing). Limited. Apply Fellowship of Postgraduate Medicine, 60, Portland Place, London, W.1. Langham 4266.

INSTITUTE OF DENTAL SURGERY

(University of London)
 Eastman Dental Hospital, Gray's Inn Road,
 London, W.C.1

A full-time postgraduate course in dental anaesthesia for medical practitioners will be held for one week from February 25 to March 1, 1952. The course will be limited to eight members, and priority will be given to candidates for the Diploma of Anaesthetics. The fee for the course will be £5. Further particulars and forms of application may be obtained from the Dean. (5920)

WEEK-END COURSE—HEALTH IN THE FACTORY. An intensive practical course for medical practitioners and nurses engaged or interested in industrial health, will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C.1 (Tel.: MUSEUM 3041), on Saturday and Sunday, February 9 and 10, 1952. Fee one guinea. Apply to the Registrar for further information. (5921)

MEDICAL CORRESPONDENCE COLLEGE, 19, Welbeck Street, London, W.1, provides COACHING for all Medical Examinations, D.A., D.P.M., D.O.M.S., D.L.O., D.C.H., D.M.R.D. and D.M.R.T., M.R.C.P., F.R.C.S., M.D. theses, and all qualifying exams by a staff of highly qualified Tutors, Honouraries and Gold Medalists. Complete Guide to Medical Examinations sent free on application. Applicants should state in which qualification they are interested.

POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS. Examination successes, 1937-1950; M.D.Lond., 62; M.B., B.S.Lond., Final, 133; F.R.C.S.Eng., Primary, 212; F.R.C.S.Eng., Final, 173; M.R.C.P.Lond., 209; M.R.C.S., L.R.C.P., Final, 303; D.A., 177; D.C.H., 135; M. and D.Obst.R.C.O.G., 232; D.O., C.P.H., D.P.H., D.L.O., D.P.M., F.R.C.S.Eng., many successes. Assistance with M.D. Thesis. Prospectus, list of tutors, etc., on application to Dr. G. E. Oates, University Examination Postal Institution, 17, Red Lion Square, London, W.C.1. Phone: HOLborn 6313.

Secretary/receptionist, 23 years, single, desires situation in medical profession, London.—Box 134, B.M.J.

Young lady, 27 (ex-W.R.N.S.), seeks position as Receptionist with doctor, Central London, good education, appearance and personality. Typing but no shorthand.—Box 160, B.M.J.

Applicants requiring testimonials, theses, copies or duplicated, should communicate with Manton Secretarial Service, Ltd., 98, Victoria Street, S.W.1 (Victoria 0141), who are specialists.

Thoroughly trained Medical Secretarial staff may be engaged through Brook Street Bureau, Ltd., 59, Brook Street, W.1, Gro. 6666, and 2, George Street, Croydon. Phone 3363.

ACCOMMODATION AVAILABLE

Portland Place, W.1. Two or three attractive flats and maisonettes to let in first-class building, also charming Mews Cottage, 3 bed, 2 bath, 2 reception, etc. Suitable combined residential/consulting room use.—Apply, Marcus Leaver & Co., 42, Sackville Street, W.1. MAYfair 4266.

CONSULTING ROOMS, ETC. AVAILABLE

Consultant desires share exceptional three-room suite. Modern house, secretary, plate, central heating, Harley Street. Rental very reasonable. Unusual opportunity young consultant.—LAN. 3325. Harley Street. Large unfurnished consulting-room, £350 inclusive. With secretary's room, £400.—Box 148, B.M.J.

Magnificent oak-panelled period consulting room with ante-room, first floor Harley Street. Vacant March quarter. Lift, central heating.—LAN. 2426. Of interest to consultants and specialists. Wimpole Street. Excellent property for disposal. Suitable for consulting rooms, or residence and practice. Twelve rooms (some inter-communicating), excluding staff and usual offices. Ready for immediate occupation. Lease 999 years from 1915. Ground rent only £50 per annum.—Goddard & Smith, 22, King Street, St. James's, S.W.1. WHITEhall 2721.

HOTELS

CORNWALL.—TREHARROCK MANOR and Farm, Jersey herd, Log fires. Come and enjoy our early spring now. Golf, St. Enodoc. Port Isaac 234.

MOTOR CARS, HIRE, ETC.

Ford Prefect 1939, black. Offers. Doctor owner.—Box 150, B.M.J.

Cash purchaser wants modern car up to 16 h.p.—Morley, 54, Streatham Hill, London, S.W.2. Tulse Hill 4489.

Gentleman urgently requires 1947-1950 Car. —Fullest particulars, Ashley, Pennington Road, Beaconsfield, Bucks (Beaconsfield 1306).

Self-Drive Hire. 49-51 cars. From £1 per day. —G. S. Hall, Ltd., 302-6, King Street, Hammer-smith W.6. RIV. 2881/2. Used cars wanted for cash.

Priority Motor Repairs Service for members of the medical profession. Mechanical and coachwork repairs, recellulosing, lubrication service and valeting. Free collection and delivery within three miles radius for repairs costing £2 10s. or more.—Mann Egerton & Co., Ltd., 68, York Way, King's Cross, N.1. Tel.: TER 7772. (Two minutes' walk King's Cross underground and main line stations.)

MISCELLANEOUS

Electrocardiograph, Cambridge Standard. Perfect condition. Suitable for hospital. Half-price. —Box 151, B.M.J.

For Sale. Disarticulated skull and bones. Complete sets physiology and pathology slides.—Box 133, B.M.J.

For Sale. "Nelson's Looseleaf Medicine," 8 vols., complete, current, as new, £35.—Box 121, B.M.J.

Bronze Name Plates with cream enamel lettering. Send size and lettering for estimate.—Osborne, 117, Gower Street, London, W.C.1.

Doctors' name plates, surgery hours, etc., engraved in brass, bronze and chromium. Leaflet and sketch post free.—G. Maile & Son, Ltd., 367, Euston Road, N.W.1.

Microscopes. Highest prices paid for good modern types. Send or bring your equipment for valuation.—Wallace Heaton, Ltd., 127, New Bond Street, W. (May 7511.)

NURSING HOMES WANTED

Institution or large Nursing or Mental Home suitable for conversion to educational offices required near London. Minimum 30,000 ft. covered space. Purchase or rent. Details in strictest confidence to Box 149, B.M.J.

NURSING HOMES FOR SALE

South Coast. Private Nursing Home, designed for fourteen psychoneurotic and border-line cases, for sale as a going concern. The main residence is a fine old house completely modernized for above purpose, in nine acres with fields for cows and a wonderful supply of fruit and vegetables. Attractive residential neighbourhood. Medical Director retiring, but will remain for introductory transition period. Apply W. Hughes & Son, Estate Agents, 1, Unity Street, Bristol 1. Telephone 21259.

infections

few drugs are successful owing to their inability to reach the site of infection.

By selecting antibacterial substances and combining them with agents which decongest, reduce discharge and promote drainage, this difficulty is overcome.

FOR THIS PURPOSE ***Ouralgicin*** ^{REGD.} WAS
DESIGNED — IT HAS PROVED PARTICULARLY EFFECTIVE.

Formula

Ephedrine hydrochloride 1.0% w/v, Benzocaine 1.4% w/v, Chlorbutol 1.0% w/v, Potassium hydroxyquinoline sulphate 0.1% w/v, Phenazone 5.5% w/v, Glycerine (Anhydrous) to 100%

Further information is obtainable from

Benger Laboratories

TONSILLITIS • INFLUENZAL COLDS • ACUTE RHEUMATISM

Control

In febrile states associated with acute rheumatism, tonsillitis, and influenzal colds, diaphoresis with subsequent drop to normal temperature and relief from painful symptoms may be expected through the systemic administration of HYPON TABLETS, in conjunction with the usual prescribed rest.

Rapid and complete disintegration ensures full therapeutic effect.

Side effects of depression and constipation are avoided.

FORMULA: Acid Acetylsalicyl. 40.22%, Phenacet. 48.00%, Caffein. 2.00%, Codein. Phosph. 0.99%, Phenolphthal 1.04%, Excip. 7.75%, (Each tablet 8 grains)

CHEMOTHERAPY OF TUBERCULOSIS

Adds a New Quality to P.A.S. CALCIUM SALT Presentation

The ONLY JUSTIFICATION for the introduction of a newer form of an already accepted tuberculostatic drug is its ability to provide additional worthwhile qualities, for example: greater convenience of dispensing, higher acceptability to patients and extra therapeutic advantage.

'Aminacyl' Granulate is a highly concentrated form of P.A.S., containing about 85% anhydrous Calcium Aminosalicylate—the latest salt to undergo successful trial—and providing the equivalent of 75% free acid P.A.S. and 9.8% calcium. Its superiority in the chemotherapeutic management of tuberculous disease is characterized by these qualities:—

CONVENIENCE *To Pharmacists* 'Aminacyl' Granulate is processed to ensure against any possibility of deterioration.

'Aminacyl' Granulate obviates the nuisance of preparing aqueous or syrupy solutions.

To Patients 'Aminacyl' Granulate is thoroughly acceptable to patients of all ages and throat types.

To Doctors 'Aminacyl' Granulate permits the physician to order any fractionated dosage; there is no "tie down" to large multiples of grammes.

STABILITY . . . 'Aminacyl' Granulate cannot deteriorate on standing over many months.

LIBERATION . . 'Aminacyl' Granulate is sialoresistant-coated to ensure that the distasteful contents are freed only after swallowing.

MODE OF ADMINISTRATION

'Aminacyl' Granulate provides effective therapeutic blood levels when administered in daily divided dosage of 12 to 15 gm. as 2 level teaspoonfuls of the Granulate (= 4 gm. free acid P.A.S.) thrice daily.

PRESENTATION: Package for one week: 100 gm. Package for one month: 400 gm. Dispensing Package: 2,000 gm.

A dosage measure (capacity 2 gm. approx.) supplied gratis with each package.

'Aminacyl' Calcium P.A.S. is also available in the form of Dragées (0.395 gm.) in bottles of 250 and 1,000; and as bulk powder.

**FOR YOUR
PREGNANT PATIENTS
WITH NAUSEA AND VOMITING**

Nidoxital

is available in bottles of 20 and 100 capsules. Original prescriptions should specify no more than 20 capsules since this quantity is usually sufficient for complete control. Dosage: one capsule 30 to 45 minutes before meals in the usual case; may be increased to 2 to 3 capsules in exceptionally severe cases.

Ortho Pharmaceutical Limited

HIGH WYCOMBE · BUCKINGHAMSHIRE · ENGLAND

Makers of Gynaecic Pharmaceuticals

For the 50% of pregnant women who suffer gastric distress, NIDOXITAL provides rapid relief. In almost all patients treated with NIDOXITAL, symptoms disappear within one to three days.*

Nidoxital

is rational therapy

Since the problem is complex, NIDOXITAL provides five effective agents for a full range of therapeutic and prophylactic action:

Benzocaine — to diminish gastric excitability
Nicotinamide — to reduce excessive peristalsis
Pentobarbital sodium — to depress central excitability
dl-Methionine — to support normal liver function
Pyridoxine — for fatty acid and protein metabolism, maintenance of nerve function and erythropoiesis. Pyridoxine is reported by many clinicians to have a favourable effect in nausea and vomiting of pregnancy and is a firmly established agent in treatment of this condition.

LITERATURE ON REQUEST

* The use of Nidoxital in Emesis Gravidarum, Am. J. Obst. & Gynec. 59: 458, 1950.

The Hypertension Syndrome

RESPONDS

*A potent alkaloidal fraction of *Veratrum viride* — biologically standardised for hypotensive activity in mammals—a new active principle not heretofore available, for the treatment of hypertension.*

Veriloid therapy produces not only gratifying objective results — significant and sustained control of elevated arterial tension — but also leads to marked subjective benefit readily detectable by the patient. As the drug takes effect, the so-called hypertension headache is relieved, impaired renal function improves, vision becomes more clear, and the associated muscular weakness is overcome.

These beneficial changes are directly attributable to the peripheral vasodilatation induced by Veriloid and the resultant improved tissue nutrition.

While individualisation of dosage is essential for maximum therapeutic benefit, in the majority of patients a response to Veriloid is usually obtained from the average daily intake of 9 to 15 mg. given in divided dosage 3 times daily. Dosage adjustment to suit the responsiveness of the individual patient can be accomplished in a week or two. Tolerance to Veriloid is not likely to develop, and treatment can be continued indefinitely without deleterious effect.

Veriloid is available on prescription through all pharmacies in 1.0 mg. tablets, in bottles of 100. It may be prescribed on Form E.C.10 without restriction. Literature available on request.

RIKER LABORATORIES LTD.,
29, KIRKEWHITE STREET, NOTTINGHAM.

The common cold

Wet and squally weather can play havoc with many forms of protective devices—among them that of normal nasal function. With this local defence out of action, the way is wide open for attack by the common cold. In such cases the worst symptoms can be allayed by the speedy application of 'Endrine.'

The three formulæ provide for the treatment of the average adult; children and sensitive patients; and those who prefer saline to an oily base.

'Endrine'

STREPTOMYCIN IN OPHTHALMOLOGY

BY

ARNOLD SORSBY, M.D., F.R.C.S.

Research Professor in Ophthalmology, Royal College of Surgeons of England and Royal Eye Hospital

J. UNGAR, M.D.

Research-Division, Glaxo Laboratories; Pathologist, Harrow and Wealdstone Hospital

AND

N. L. BAILEY, M.B., B.Ch., D.O.M.S.

Lately House-surgeon, Royal Eye Hospital, London

Tuberculous lesions of the eye and infections by Gram-negative bacilli constitute the two groups for which streptomycin therapy would be indicated on theoretical grounds. The cases diagnosed as tuberculous are a composite group. Tubercle bacilli, or typical giant-cell formation, can be demonstrated in tuberculous conjunctivitis, but for the mass of lesions diagnosed as tuberculous keratitis and tuberculous iritis no such definite evidence is generally available. The diagnosis in such cases is usually on clinical grounds, with very variable supporting evidence. As for infections by Gram-negative bacilli, these are on the whole infrequent, the outstanding examples being infection of the cornea by *Pseudomonas pyocyanea* and by *Proteus vulgaris*. Here bacteriological evidence is readily available. Apart from being easily established bacteriologically, the clinical picture that these Gram-negative bacilli give in the cornea is characteristic. Instead of the classical serpiginous corneal ulcer and hypopyon, there is a corneal ulcer with a sloughy base, frequently heaped up, and generally extending as, infiltrates well into the surrounding corneal tissue; hypopyon is not a characteristic concomitant, but is not exceptional and is apt to appear very dense. These corneal infections do not respond to the sulphonamides or penicillin, and they run a rapid and disastrous course, often leading to opacification of the whole of the cornea and to perforation.

It is generally accepted that tuberculosis of the conjunctiva, cornea, iris, and retinal veins is secondary to a general infection. This does not exclude local therapy as an agent of some value, but does emphasize that exclusively local therapy is unlikely to prove satisfactory. In the case of infections with Gram-negative bacilli the lesion is exclusively local, and local treatment may therefore be expected to give the desired results.

In the present study an attempt has been made to establish the levels of concentration that can be reached in the eye by the systemic and subconjunctival injection of streptomycin; the efficacy of such administration in experimental infection of the cornea by *Ps. pyocyanea* has been investigated; and we have tried to evaluate the use of streptomycin clinically.

Experimental Studies

(a) Ocular Tolerance of Streptomycin Injected Subconjunctivally

The purified streptomycin salt at present available is soluble to the extent of 0.5 g. in 1 ml. of water. The solution thus obtained is well tolerated by the rabbit when injected subconjunctivally—in fact, very much better than 1,000,000 units of penicillin similarly given.

There is nothing to be gained by giving smaller doses subconjunctivally. Larger doses cannot be given, as more than 0.5 g. does not go into solution in 1 ml.

(b) Levels of Concentrations Reached in the Eye by the Systemic and Subconjunctival Injection of Streptomycin

Method.—Rabbits weighing 2.5–3 kg. were used for the tests. Dihydrostreptomycin sulphate was injected in three ways: (1) 50 mg. per kg. was injected in 2 ml. of physiological saline intramuscularly; (2) 500 mg. was injected in 1 ml. of distilled water subconjunctivally; and (3) 500 mg. was injected in 1 ml. of 1:1,000 adrenaline subconjunctivally. At appropriate times the animals were killed by the intravenous injection of pentobarbitone sodium and the eyes removed. In the case of the animals treated by intramuscular injection, both eyes were taken and treated as one. They were given a rapid rinse in sterile saline and were then immediately dissected. The aqueous humour, vitreous humour, anterior tissues, posterior tissues, and cornea were separated, minced with scissors, and after weighing were extracted with an appropriate amount of pH 8 phosphate buffer. Samples of blood were removed from the left ventricle of the animals just before death. The extracts and the blood samples were titrated for streptomycin content by either the capillary-tube method with *Bact. friedländeri* or by plate assay method using *Bacillus subtilis*.

The results are recorded in Table I.

The following points may be noted: (1) Intramuscular injection of 50 mg. per kg. in the rabbit is equivalent to approximately an intramuscular injection of 4 g. in an adult patient—well beyond the toxic limit. With this dose it will be noted that levels at four hours and subsequently are *nil* in the vitreous and cornea, whilst the aqueous gives a level of only 0.3 µg. at four hours. The levels at two hours are also not high. (2) A subconjunctival injection of 500 mg. in 1 ml. of water gives considerable levels in the aqueous and vitreous,

TABLE I.—Ocular Concentrations of Streptomycin in the Rabbit After Administration by Different Routes

Route and Dose	Time (hours)	Streptomycin Levels ($\mu\text{g./ml.}$ or $\mu\text{g./g.}$)					
		Blood	Aqueous	Vitreous	Ant. Tissues	Post. Tissues	Cornea

	24	5.3	164	2.3	164	47.5	282
	28	1.5	>28				3.5
	36		264	15.3	112	30	900
	48		>40				3.3
			87.5	4.53	117	57	283
		<0.37	<0.74	<0.37	3.1	10.25	<1.85

persisting for about 12 hours. (3) A striking feature is the markedly increased initial intraocular concentrations when streptomycin is dissolved in adrenaline 1 : 1,000 instead of water, and the considerably longer persistence of these levels : at 36 hours the levels are still significant.

These findings are of the same order as those recorded for penicillin: subconjunctival injection gives higher levels than intramuscular injection, and the levels become both higher and more persistent when adrenaline is added to the solvent.

(c) Experimental Infection of the Cornea with *Ps. pyocyanea*

Method.—Thirteen rabbits were used. The cornea of the right eye of each rabbit was scarified with a scalpel blade and infected with two loopfuls (3-mm. diameter loop) of a suspension of *Ps. pyocyanea* (24-hour agar culture of strain 150 E), the suspension being rubbed into the scarified area with the loop for about 15 seconds. Three of the animals were kept as controls. The remaining 10 were treated three hours after infection by the injection, subconjunctivally into the infected eye, of 0.5 g. of dihydrostreptomycin sulphate in 1 ml. of 1:1,000 adrenaline. A single dose only was given. The course of the infection

was followed in all of the animals by daily inspection. The heavily infected control animals were killed on the sixth day, when the corneae had perforated.

The results in this experiment are summarized in Table II.

It will be seen that the three control animals all showed the disastrous course characteristic of *Ps. pyocyanea* infection in the rabbit. The 10 animals treated with a single subconjunctival injection of 0.5 g. of streptomycin in adrenaline 1 : 1,000 gave eminently satisfactory results. By the third day only two of these ten had not recovered fully. By the fifth day one of these two had become normal. The damage in the one animal that had not responded fully was almost negligible.

Clinical Experiences

The clinical results recorded here have been collected over the past three years. In the earlier stages purified streptomycin was not available and dosage was hampered by irritative reactions. In all, streptomycin was used systemically or locally in 53 cases, which fall into four clinical groups :

Group I.—Cases with a definite bacteriological or histological diagnosis. These comprised tuberculous conjunctivitis, acute conjunctivitis, dacryocystitis, infected corneal ulcer, and one case of intraocular infection, all due to Gram-negative bacilli or to penicillin-resistant organisms.

Group II.—Cases presumed to be tuberculous on good clinical grounds. This group consisted of three cases of tuberculous keratitis.

Group III.—Cases presumed to be tuberculous on indefinite clinical grounds—Eales's disease, iridocyclitis, and scleromalacia perforans.

Group IV.—Cases of tuberculous allergy—phlyctenular ophthalmia.

Group I. Cases with Definite Histological or Bacteriological Diagnosis

(a) *A Case of Tuberculous Conjunctivitis.*—A child aged 5½ had a large sloughing ulcer in the inferior fornix of the left eye; biopsy showed it to be tuberculous, with tuberculous giant-cells and caseation; tubercle bacilli were demonstrated in the smear of the guinea-pig inoculation. Treatment with intramuscular streptomycin, 0.5 g. a day for 30 days, caused rapid resolution of the lesion clinically, but, histologically, cure was much slower. Biopsy three months later showed fibrous tissue with a few epithelioid cells, while guinea-pig inoculation

TABLE II.—Treatment of *Ps. pyocyanea* Infections of the Cornea in Rabbits with Dihydrostreptomycin Sulphate in Adrenaline

Rabbit No.	Treatment	Appearance of Infected Eye after Infection

was negative. When seen recently, 18. months later, there was no sign of the lesion beyond fibrosis, and there had been no relapse.

(b) *Six Cases of Acute Conjunctivitis*.—All cases were due to *Proteus vulgaris* except one case, which produced a penicillin-resistant staphylococcus after prolonged local penicillin therapy. Four cases were initially treated by other drugs which had no effect; two cases, in which the smear showed Gram-negative organisms, were started on streptomycin immediately. Two cases were treated with drops (in a concentration of 0.5 g. per ml. instilled at half-hourly intervals), three with ointment (0.1 g. per g.), and one, following a cataract extraction, with subconjunctival streptomycin (0.5 g. in 10 min. (0.6 ml.) of water and 5 min. (0.3 ml.) of adrenaline 1:1,000). All cases cleared up quickly. The results were comparable to those seen with local penicillin therapy in conjunctivitis due to penicillin-sensitive organisms.

(c) *A Case of Acute Dacryocystitis*.—This was a severe recurrence of a typical acute dacryocystitis which did not respond to four days of systemic penicillin, in the last two of which the sac was also syringed with penicillin. Systemic streptomycin therapy (0.5 g. a day for five days) led to a rapid and uninterrupted recovery, the sac remaining patent. The organism proved to be *P. vulgaris*.

(d) *Nine Cases of Infected Corneal Ulcer*.—Six cases occurred within five days of having had a corneal foreign body; one was an ophthalmia neonatorum; one was a secondary infection of a dendritic ulcer; and one was a case of marginal ulcer of unknown cause. The organisms in these nine cases were *Ps. pyocyanea* in two cases, Gram-negative bacilli in three cases, and *P. vulgaris*, *Bact. coli*, *B. xerosis*, and bacillus of Patel in one case each. All but two cases were given daily subconjunctival injections of 0.5 g. of streptomycin within two or three days of the start of infection; one case had been worsening for three months, and in the other, the baby with ophthalmia neonatorum, treatment by drops and intramuscular injection was started 10 days after onset, there having been very slight improvement on systemic sulphonamide for six days. Two cases had been started on streptomycin immediately, one having been diagnosed as a Gram-negative type of infection clinically and confirmed bacteriologically next day, 24 hours thus being saved; while the other showed Gram-negative bacilli in the smear. Five cases had one dose of subconjunctival penicillin (1,000,000 units) on admission, the nature of the infection not being known till 24 hours later, from the culture. The conjunctiva became friable after repeated subconjunctival injections, and, when it would hold no more, streptomycin was given retrobulbarly. This is probably less effective.

The Subconjunctival Injection.—The dose was at first 1 g. of streptomycin in 2 ml. of fluid, but this has been reduced to 0.5 g. in 1 ml. The solvent used is, as for subconjunctival penicillin—a stock solution, 10 min. (0.6 ml.) of which contains 1/40 gr. (1.6 mg.) of atropine sulphate and 1/8 gr. (8 mg.) of cocaine hydrochloride. To 10 min. (0.6 ml.) of this solution is added 5 min. (0.3 ml.) of adrenaline 1:1,000 before injection.

Results.—All cases were left with a quiet eye, except the one which was hopeless to begin with and became quiet only after perforating. Three cases had a poor visual result of 3/60 or less, due to dense corneal scarring owing to the severe initial damage before streptomycin treatment was instituted. The remaining

cases obtained a good visual result, the corrected visual acuity being 6/9, 6/12, and 6/12 in three cases, and 6/36 under a mydriatic in a patient who could not be followed up. The baby with ophthalmia neonatorum had a thin residual scar.

(e) *A Case of Post-operative Intraocular Infection*.—A man with a right detached retina had a lens extraction for traumatic cataract in the other eye while under systemic penicillin and local treatment to control an intractable otorrhoea. Forty-eight hours after operation subconjunctival streptomycin, 0.5 g., and systemic streptomycin, 0.5 g., were started, as the anterior chamber was infected; treatment was continued for five days. The infection subsided and some useful vision may be expected after needling.

Group II. Cases Presumed to be Tuberculous on Good Clinical Grounds

Three Cases of Tuberculous Keratitis.—Three typical cases with long histories were treated for one or two months with between 2 g. and 0.5 g. of intramuscular streptomycin daily, the dosage tending to decrease while the duration of the course tended to increase. All cases improved markedly within a fortnight, and in one case the result was particularly striking: the visual acuity improved from hand movements in both eyes to 6/60 in the right eye and 6/9 in the left eye—very much better than it had been for years. These three cases have now remained quiet for periods of 10, 19, and 26 months respectively.

Group III. Cases Presumed Tuberculous on Indefinite Clinical Grounds

(a) *Four Cases of Eales's Disease*.—Four cases presented as Eales's disease: only one case showed (in a chest radiograph) any further evidence of tuberculosis. These patients were given systemic streptomycin for one or two months, with between 2 g. and 0.5 g. of intramuscular streptomycin daily, the dosage tending to decrease with a longer course. The results are dubious and indefinite. The most that can be claimed is the absence of relapses in three cases which seemed quiet or quiescent at the start, while the one active case has become worse.

(b) *Five Cases of Iridocyclitis*.—Four of these five cases had a common history of slowly worsening iridocyclitis for over six months, with the development of mutton-fat K.P., before streptomycin was started; in the remaining patient there was a history for only two months. Two of these cases had further indications of a possible tuberculous origin—tuberculous pleurisy in the one, and a strong family history of tuberculosis in the other. Two patients, both young women, developed retinal vasculitis. All received one dose of streptomycin, 0.5 g. a day for a month intramuscularly, except one patient who had side-effects necessitating its discontinuance after 17 days. One patient has shown only slight improvement, and it is now three months since she had the course; another became completely clear only seven months after the course; two patients who developed secondary glaucoma and pain just before the course had (three months later) normal tension and no pain, and the K.P. had become thinner and crenated. The patient who had had an incomplete course owing to toxic effects now has only a slight aqueous flare in both eyes, but, as she responded to x-ray therapy shortly after the streptomycin was discontinued it is impossible to say to which treatment (if to either) her improvement should be attributed.

(c) *Iridocyclitis with Nodules*.—Of three cases, one, that of a woman aged 20 with multiple nodules in one iris—the whole reaction strongly suggestive of sarcoidosis—showed no response to systemic administration of streptomycin. The two other cases, with an isolated nodule in each instance, appeared to improve. Steady diminution of the nodule was observed during a month's treatment by intramuscular injections of 0.5 g. daily, but the improvement has not been maintained. In one case the nodule is still as large as before, and in the other there is a recurrent iridocyclitis.

(d) *Three Cases of Scleromalacia Perforans*.—These cases, which had been progressing steadily, were given 0.5 g. of streptomycin systemically six-hourly for 28 to 56 days. In none was there any improvement.

Group IV. Cases of Tuberculous Allergy: Phlyctenular Ophthalmia

Children with phlyctenular ophthalmia were found to improve quickly on mydriasis and an open-air regimen at White Oak Hospital. Seventeen cases were given systemic streptomycin in addition, because they either showed no response or relapsed repeatedly. Fourteen cases had active lesions when the course was started—nine for at least two months and five for three weeks or less. Four of these children had long histories of repeated relapses. In addition streptomycin was given to two cases which had shown frequent relapses but were then quiet, and to one case which was almost quiet before the course started.

The diagnosis, made on clinical grounds, was supported in 15 cases by one or more of the following features: positive Mantoux reaction, a positive chest x-ray finding, and a family history of tuberculosis.

At first streptomycin was given on a basis of 20 mg. per lb. (0.45 kg.) body weight a day in divided doses for a week, but later in the investigation the amount of the drug was reduced, and it was given in one daily dose over a longer period, the ultimate dosage used being 10 mg. per lb. (0.45 kg.) a day for 56 days.

In the acute case streptomycin proved of value in cutting short the acute attack and possibly also in preventing recurrences. The results in the 14 active cases may be tabulated as follows:

Activity under Control Within	No. of Cases	Relapses Within 3 Months	No. of Cases	Follow-up Results After First 3 Months of 13 Controlled Cases	
				Quiet for	No. of Cases
7 days	2	No relapse	5	24-28 months	3
10 "	5	One "	3	18-24 "	3
21 "	4	Two relapses	3	12-18 "	3
28 "	1	Three "	2	Relapse: a year later	1
56 "	1	Uncontrolled	1	Not known—trace lost	3
Uncontrolled	1				
	14		14		13

The results in the three cases treated during the quiescent stage in the hope of controlling their tendency to frequent relapses were: (1) Frequent recurrences for the 21 months under observation in one case, but the attacks were probably milder. (2) Three relapses in the two months following the course and three more in the four months subsequent to a second course. Since then quiet for 18 months. (3) No relapse for four months after a course of treatment—in contrast to three attacks in two months before treatment.

Discussion

The excellent results achieved with penicillin in infections of the eye due to penicillin-sensitive organisms have thrown into sharp relief those infections, largely due to Gram-negative bacilli, for which penicillin is ineffective. Some cases of acute conjunctivitis and acute dacryocystitis are caused by penicillin-insensitive organisms, but the more threatening of the acute lesions is infection of the cornea by Gram-negative bacilli. These run a rapidly destructive course, for the corneal reaction is essentially a proteolytic phenomenon consistent with the proteolytic properties of these organisms.

The recognition of Gram-negative infection of the cornea as a characteristic clinical entity calling for specific treatment appears to have been anticipated by the older literature. The concept of corneal abscess of the older literature does not seem to have been well defined, the term being used for corneal ulceration with diffuse infiltration as well as for interstitial corneal reaction without ulceration. It is likely that what went under the name of corneal abscess included the group of infections of the cornea by Gram-negative bacilli stressed here. In so far as it emphasizes the interstitial reaction of the cornea, that designation was most useful. The complete clinical picture appears, however, to require equal stress on the sloughy, heaped-up base of these corneal ulcers.

The experimental evidence from infection with *Ps. pyocyanea* that such infected ulcers respond well to streptomycin is supported by the limited clinical experience reported here, and it may be assumed that with early and adequate streptomycin treatment these corneal infections will respond as readily as serpiginous ulceration responds to penicillin. Whilst the experimental results were obtained with 1 ml. of adrenaline as the solvent, clinically it would not be safe to use so much adrenaline. For this reason it would be best to use 10 min. (0.6 ml.) of water and 5 min. (0.3 ml.) of adrenaline. The solvent can readily be adjusted to give a mydriatic effect by incorporating 1/8 gr. (8 mg.) of cocaine hydrochloride and 1/40 gr. (1.6 mg.) of atropine sulphate in the 10 min. (0.6 ml.) of water. A stock solution containing these ingredients is easily prepared, and keeps well, but it is essential that the adrenaline should not be added to the solvent until use.

The value of streptomycin in the tuberculous infections of the eye is not so definite, if only because diagnosis is frequently uncertain. Judging by the proved case of tuberculous conjunctivitis recorded here, as also by the cases of presumed tuberculous keratitis, systemic treatment is of considerable help. Whether these cases should not in addition be treated by local applications is an open question. The results in phlyctenular ophthalmia are also hopeful. Here there seems less reason for local treatment. The disappointing results obtained in plastic and nodular iritis, presumed to be tuberculous in origin, and in Eales's disease, may arise from inadequate use of streptomycin or from a fallacious aetiological interpretation.

Summary

Streptomycin, 0.5 g. in 1 ml. of water, is well tolerated on subconjunctival injection.

Such doses give considerably higher intraocular levels when injected subconjunctivally than on intramuscular injection.

The intraocular levels are higher still and persist up to 36 hours if adrenaline 1:1,000 is the solvent.

In the experimental animal a destructive *Ps. pyocyanea* infection of the cornea is fully controlled by one subconjunctival injection of 0.5 g. of streptomycin in 1 ml. of adrenaline 1:1,000.

For clinical purposes streptomycin to be injected subconjunctivally should be dissolved in 10 min. (0.6 ml.) of water to which 5 min. (0.3 ml.) of adrenaline 1:1,000 is freshly added.

Clinically, streptomycin is effective when used subconjunctivally in infections of the cornea due to Gram-negative bacilli. As these lesions are highly destructive, early treatment is essential, and the characteristic clinical appearance of such infections facilitates early diagnosis. Streptomycin locally is also invaluable in acute conjunctivitis due to Gram-negative bacilli.

Systemic streptomycin therapy has proved helpful in tuberculous keratitis. It has given poor results in presumably tuberculous iridocyclitis and in periphlebitis. In phlyctenular ophthalmia it tends to cut short severe attacks, and probably reduces the frequency and severity of relapses.

Our thanks are due to Dr. P. D'Arcy Hart and the Medical Research Council for liberal supplies of streptomycin during the earlier stages of this investigation, when the material was not readily available. We are obliged to Sister Thorogood and her staff of the Royal Eye Hospital unit at Lambeth Hospital and to Sister Condon, formerly of White Oak Hospital, for their help in the treatment of patients. To Dr. P. Muggleton and Mr. B. I. Helliwell, of Glaxo Research Laboratories, we are indebted for technical assistance.

THE CLINICAL FEATURES OF THE PNEUMONIAS UNDERGOING VIRUS TESTS

BY

G. H. JENNINGS, M.D., F.R.C.P.

Senior Physician, Edgware General Hospital

The response of the pneumonias to sulphonamides and penicillin has broadened rather than solved the problem of the differential diagnosis and treatment of lung consolidations. Since such treatment has been introduced, a wide group of non-bacterial pneumonias caused by viruses and rickettsias has been revealed. American authorities have stressed the increasing incidence of virus pneumonias, Goodrich and Bradford (1942) finding them almost as frequent as pneumococcal pneumonias, and Reimann (1943) computed figures of 70% of all pneumonias for this group. The process of sorting out the various non-bacterial pneumonias is not yet far advanced, and while influenzal pneumonias and the pneumonias of psittacosis, lymphocytic choriomeningitis, glandular fever, lymphogranuloma venereum, and Q fever have emerged as definite entities other similar pneumonias await identification.

The group of "primary atypical pneumonia, aetiology unknown," has been considered by some as an entity (Joules, 1950); but this has been denied elsewhere (Scadding, 1948). In the last-named condition the non-specific cold agglutination reaction has been used as a diagnostic test; in the other pneumonias mentioned the diagnosis is confirmed by the detection of specific antibodies by complement-fixation and neutralization tests. A rise in antibody titre in these tests is diagnostic and is

particularly valuable in influenza, in which it is often impossible to obtain the virus from the patient's nose or throat and so to isolate it by ferret inoculation.

The complement-fixation test was the one employed in the series of cases described below, and most of the cases were also examined for complement-fixing antibodies of *Rickettsia burnetti*, psittacosis-ornithosis and lymphogranuloma viruses, and by *Streptococcus M.G.* agglutination. Where possible the tests were done on acute and convalescent phase sera, but in some cases only convalescent sera were obtainable. These tests were performed by Dr. B. P. Marmion, Dr. A. D. Macrae, and Dr. A. P. Goffe, of the Colindale Group Laboratory. Cold haemagglutination tests were also done on many of the cases at the Edgware General Hospital by Dr. E. D. Hoare. Nearly every case was questioned and examined by me so as to obtain a uniform approach to the clinical aspects of these cases of pneumonia. This paper is a review of the clinical findings in 159 of such cases seen in the Edgware General Hospital between the beginning of January, 1949, and the end of May, 1950.

Clinical Investigation

It soon became apparent that clinical methods did not readily distinguish the various forms of pneumonia, so all cases of suspected lung consolidation seen during the investigation were serologically tested. The cases are divided into two groups, the first being seen between January 1 and September 1, 1949, and the second group between early November, 1949, and the end of May, 1950. A fairly severe outbreak of influenza (mainly of the A type) is included in the first group, and the second group covers a lesser outbreak of influenza B in March and April, 1950. While the patients were being submitted to the tests just mentioned special consideration was also given to certain features: the history and symptoms of the illness; a past history of chest infection; the signs of the illness; the duration of the fever; the x-ray findings; the white cell counts; the sputum examinations; and the nature of any complications.

The two groups showed very similar numbers of cases, 88 being examined in the 1949 group, and 71 in the 1949-50 group. The cases were all of severe respiratory disorder, and either showed clear pneumonic signs or had such symptoms of lung involvement that pneumonia was immediately suspected. The patients had all been active till the onset of the illness, even though some had old respiratory or cardiac disease, and the rapid development of severe symptoms, often of sudden onset, was a feature in all. The composition of the two groups as determined by the special tests is shown in Table I, the

TABLE I

	Group 1 (1949)	Group 2 (1949-50)
Influenza (confirmed)	16	18
" (probable)	22	—
Primary atypical pneumonia	11	11
Psittacosis-ornithosis	—	2
Unclassified	39	40
Total	88	71

"primary atypical pneumonias" being the cases in which a cold agglutinin titre of 1 in 16 or over was reached. The cases classified as definitely positive influenzas were those which showed a rise of influenza antibody titre between the acute and convalescent phases; if a signifi-

cantly high titre was found only in the convalescent phase the case was listed as "probable positive." Neither of the psittacosis-ornithosis cases appeared to have been exposed to avian infection. No case of Q fever was detected during the whole investigation.

The age distribution in the two groups is shown in Table II, and a remarkable similarity is noticeable. Thus

TABLE II.—Age Distribution

Age Groups (Years)	Group 1					Group 2		
	Infl. (Confirmed)	Prob. Infl.	Total Infl.	Primary Atypical Pneumonia	Uncl.	Infl.	Primary Atypical Pneumonia	Uncl.
0-9	1	1	2	0	2	0	0	1
10-19	1	5	6	1	2	0	0	3
20-29	1	1	2	3	2	2	2	4
30-39	3	0	3	2	7	3	3	5
40-49	3	5	8	3	4	4	3	4
50-59	6	5	11	1	10	2	1	13
60-69	1	4	5	0	8	7	1	9
70+	0	1	1	1	4	0	1	1
Totals	16	22	38	11	39	18	11	40

25 (65.8%) of the influenza cases of group 1 were over 40, and 13 (72.2%) of those in the second group were over 40. Of the unclassified cases 26 (66.6%) in group 1 and 27 (67.5%) in group 2 came in this age category. The primary atypical cases were fewer and also on the average younger than those in the other groups; thus 8 (72.7%) in each group were between 20 and 50. The influenza figures correspond with the observations of Stuart-Harris *et al.* (1950) on influenzal cases in Sheffield, many of his cases being in the older age groups.

During the investigation five patients died in group 1 and three in group 2. These figures, which are a striking testimonial to modern treatment, become even more remarkable when the ages of the patients and other associated conditions are considered. Thus in group 1 four patients with "probable" influenza (high complement-fixation titre at the only reading available) died; one of these was 75 and another 60; the third had a contracted horseshoe kidney and uraemia; and the fourth, a boy of 12, an old case of poliomyelitis, had widely paralysed respiratory muscles. One unclassified patient aged 63 died during the first half of the investigation. Of the three fatal cases in group 2 one aged 68 had probable psittacosis-ornithosis; another, a chronic bronchitic with emphysema, aged 52; had a suprarenal haemorrhage, and the third was admitted after six weeks' illness with organizing suppurative pneumonitis.

During the influenza B epidemic period four serologically uninvestigated patients (not included in Table I) died within a few hours of their admission, and three of them, aged respectively 21, 46, and 65 years, had sudden illnesses of influenzal type. All three failed to show influenza virus from lung culture on fertile hen's egg, but all showed a free growth of *Staph. aureus*—a possibly significant finding. The husband of the youngest of these was said to have had influenza a short time previously. The fourth, aged 69, proved to be a long-standing chronic bronchitic with a large area of grey hepatization. Thus among 159 patients with pneumonia who lived long enough to have some treatment and investigation there were eight deaths, usually facilitated by some disease other than the pneumonia, and there were four other deaths of patients in whose case there was no time for effective therapy.

Onset

A comparison between the influenzal cases and the various non-influenzal cases was attempted on the lines mentioned above. Stuart-Harris *et al.* (1938) had underlined the significance of a sudden onset as a feature of the influenzal infections; but in our investigation, which was mainly concerned with ill pneumonic cases, it was possible that this feature might be somewhat obscured. The figures given in Table III, however, show that this

TABLE III

	Sudden Onset	Possibly Sudden	Gradual
Group 1:			
Influenza	14	2*	0
Probable influenza	17	3	2
Primary atypical pneumonia	6	2	3
Unclassified	15	5	19
Group 2:			
Influenza	11	3	4
Primary atypical pneumonia	7	1	3
Unclassified	13	5	22
Psittacosis	1	0	1

* Both bronchitic cases.

observation holds good, particularly amongst the influenzal cases of group 1. (These were mainly due to the A type of infection, only six B type infections being found.) Only in two of the "probable" cases of this year did the illness appear to have a gradual onset, and in one of these, a girl of 21, recent tuberculosis was also found; the other was an old bronchitic case. Many of this first series were admitted within a week of the onset of the illness. All the cases in group 2 found to be influenzal were of the B type; they were admitted on the average later in the illness, but, even so, only four had symptoms of seemingly gradual onset, and of these one was a case of gross mitral stenosis and two had illnesses of two and six weeks' duration. Thus in only one of the four was the true onset of the infection clearly discernible.

But sudden onset is not confined to influenzal pneumonias, as is clearly shown in Table III. It is noteworthy that over one-third of the "negative" unclassified cases in the two years should have had onsets very difficult to distinguish from influenza. This finding is one of those which encourage the belief that there are other respiratory viral infections yet to be identified. Of the two psittacosis-ornithosis cases the more strongly positive also showed a sudden onset.

Severe headache is regarded as a distinguishing feature of "primary atypical pneumonia," but only half our cases in this group showed this symptom, while headaches of varying severity were seen in just over a quarter of the influenzal and in nearly a third of the unclassified cases.

The frequent occurrence of two phases of onset of the illness is also remarkable in all the groups of cases, 28 of the 1949 cases and 27 of the 1949-50 cases showing this feature. In them, after a beginning usually "influenzal" and sudden; there was a period of malaise followed by partial improvement; then, sometimes after the patient had been active, the illness returned with redoubled force and usually with symptoms suggestive of lung involvement, such as chest pain, dyspnoea, and severe cough. The interval between the two phases ranged from two days to three weeks, but in many cases was about one week. The average length of the interval

was slightly more in the unclassified cases (ten days) than in the influenzal and primary atypical pneumonic cases (seven or eight days). The expected evidence of a bacterial invasion to account for the second phase was not forthcoming in more than two-thirds of these cases, and in them the progressing invasion by the viruses, facilitated by inadequate rest, probably explains the advance of infection.

It is also noteworthy that no influenza-positive case showed cold agglutinins and no case with cold agglutinins showed a positive influenza complement-fixation reaction.

Respiratory Symptoms

Stuart-Harris *et al.* (1938) also emphasized the greater preponderance of malaise and general symptoms over respiratory symptoms in the influenzal cases, though he also seemed to imply that coryzal and non-exudative pharyngitis were common features in influenza. But we found pharyngitis in only 5 to 10% and coryza in less than 20% of all our cases, and laryngitis was conspicuous by its absence. The fact that the cases had usually passed to a pulmonary phase in the disease, and that mental hebetude may have caused some of the patients to forget such early symptoms, does not account entirely for the lack of prominence of these symptoms. On the other hand, our influenzal pneumonias were like those of Scadding (1937) in not being prominently dyspnoeic—except in the rare fulminating cases—but they often showed light cyanosis and a very great deal of toxic apathy and asthenia. And the non-influenzal cases in many instances gave a clinical picture indistinguishable from this.

Before considering the other respiratory symptoms, the effect of preceding respiratory disorders in these cases cannot be overlooked. Thus an old bronchitic case developing influenza naturally soon tended to show an exacerbation of bronchitic symptoms, while an asthmatic was liable to show in addition marked bronchial spasm and wheezing. In such cases dyspnoea was often severe and cyanosis pronounced, and in them the sudden type of onset was less in evidence. The proportion of cases with preceding chronic bronchitis was as great amongst the influenzal cases during the two outbreaks as amongst the other pneumonic cases investigated. The only group in which chronic bronchitis was not a marked feature was the "primary atypical pneumonic" group, and, as has already been pointed out, the average age was lower in this group than in the others. Pleuritic pain was an early feature in from one-half to two-thirds of the cases in each category.

Generally speaking, the symptoms failed to distinguish the influenzal cases from non-influenzal pneumonic cases, an observation in line with those of Francis (1941) and other observers in the United States (Horsfall *et al.*, 1940; Sulkin *et al.*, 1941). Dingle and Abernethy and their co-workers (1948) in the U.S. Commission on Respiratory Diseases worked in two U.S. Army camps and failed to distinguish influenzal cases from other acute respiratory diseases by ordinary clinical methods. While they found sore throat and sputum commoner earlier symptoms in acute respiratory diseases, and sudden onset, muscular aches, and prostration commoner in influenza, such differences were not consistent enough to permit a clear separation. A survey of the results of our case symptoms showed that despite treatment there was a greater tendency to prolonged fever of over one week in the influenzal and "primary atypical pneumo-

nic" cases. As all cases on admission were given full therapy with sulphonamides, and often with penicillin as well, and as resistant bacteria were rarely encountered, this tendency to prolonged fever may in these cases well have been a sign of viral infection.

Analysis of Physical Signs

Before making a comparison of physical signs in the two groups it is interesting to recall the old anatomical division of pneumonias into bronchopneumonias and lobar pneumonias. If an influenzal outbreak occurs the affected cases are likely to be further infected with the prevailing bacteria of the locality, and if these are pneumococci, lobar pneumonic manifestations are likely to be frequent. While a pure pneumococcal lobar pneumonia was once of apparently common occurrence, this is not so to-day, and in our series of 159 cases only one case without evidence of recent viral infection fulfilled all the criteria of lobar pneumonia as regards history, signs, radiological appearance, leucocytosis, and pneumococcal sputum. It is not improbable that pneumococci have been rendered less pathogenic and less widespread by the effective therapy of recent years, but it is also probable that "lobar pneumonias" could on past occasions have been viral pneumonias secondarily infected by pneumococci.

In our cases of the first group seven of those which were an established recent infection with influenza and ten with a probable recent infection showed large areas of dullness, bronchial breath sounds, and rales, and so might have been classified as lobar pneumonia. The signs were unilateral or bilateral and were usually basal. Similar findings were made in 15—a similar proportion—of the unclassified cases. The findings in the second group of cases were very similar, and in both years there was one influenzal case in which the lung consolidation had broken down under the influence of *Staph. aureus* and had produced cavernous signs, apical in one instance and basal in another. Scadding (1937) has mentioned the cases in which the dullness to percussion is associated with an absence of breath sounds sufficient to suggest fluid. These cases were fewer in the Edgware series—only one among the influenzas, three among the probable influenzas, and seven among the unclassified cases. In a small proportion of these early cases pleural fluid, usually in small quantities, was actually present, but more usually it appeared later, masking previous typical pneumonic signs.

Scadding has also commented on a stage of influenzal lung infection where patches of slight percussion impairment, weak breath sounds, and adventitia unassociated with x-ray changes are found. In these he considers lung oedema to be present, and of those in group 1 we found nine among the established and probable influenzas—one cold-agglutinin positive and eight among the unclassified cases. Nine of the influenzal cases (including the "probables") and ten of the unclassified cases in group 1 showed merely bronchitic signs, unilateral or bilateral rales or rhonchi, or both, without percussion impairment. These cases included a number of chronic bronchitics, but it also must be emphasized that radiological evidence of consolidation occurred more often than could be elicited by physical signs.

The figures for group 2 were largely similar in all instances, and it is evident that influenzal cases cannot be separated from non-influenzal by mere consideration of physical signs.

Scadding (1937) has classified the lung involvement in influenzal pneumonia as follows: (a) Cases without clinical signs of lung involvement; (b) cases with lung signs but without consolidation; and (c) cases with demonstrable consolidation. The last two groups he has further subdivided according to their extent and severity. By use of his criteria, and making allowance for the presence of a number of borderline cases, the extent of lung involvement in our cases is shown in Table IV. It should be explained that, whereas C1 and C2 represent respectively consolidation and more extensive consolidation of patchy nature, C3 cases are those with much bronchitis as well as lobar consolidation, and C4 are cases of purely lobar type.

Table IV further shows the impossibility of separating the cases of the various categories on the basis of clinical signs. As will be seen, this difficulty extends to the so-

TABLE IV.—Extent of Lung Involvement (Scadding's Classification)

	1949				1949-50		
	Infl.	Prob. Infl.	Cold Agglut. Positive	Unclassified	Infl.	Cold Agglut. Positive	Unclassified
A	0	0	1	1	0	0	0

B2	6	3	1	8	3	0	7
C1	6	12	7	21	10	10	19
C2	3	6	2	6	0	0	10
C3	0	0	0	0	0	0	0
C4	0	0	0	2	0	0	1
	16	22	11	39	18	11	40

called primary atypical pneumonias, though, as often noted in the past, these tended to show signs disproportionately small for the amount of consolidation. They also twice showed an extrapulmonary feature peculiar to them in this investigation—namely, conjunctival injection.

An approximate correlation of the physical signs with the radiological findings is discussed in the next section.

Radiological Appearances Correlated with Physical Signs

In all groups these varied greatly, and it can be said at the outset that they did not have any conclusive power in separating cases in the various groups. As might have been expected, prominent bronchial shadows of a linear and branching type were a feature of the bronchitic cases (B1 and B2 of Scadding's classification). A closer-knit reticulation and a very fine mottling in the more affected areas—often basal—was the next degree. These cases and the more definite pneumonias with larger areas of mottling (C1 of Scadding) usually produced a variable degree of percussion-note change with weakened breath sounds and rales at one or both bases. The reticular and mottled appearances were found in all classes of the pneumonias investigated.

A curious dense haze in the lungs, sometimes referred to as a "ground-glass" shadow or "partial" consolidation, was also seen in cases in all groups. The bronchial markings could often be seen through it, and even when extensive it usually spared the lung periphery. There was often with it a history strongly suggestive of viral pneumonia, and it occurred noticeably in the "primary atypical pneumonia" series. The signs were often those of moderate percussion-note change, distant tubular breath sounds, and fine rales, but, like all the other

radiological appearances of pneumonia, this partial consolidation was associated with variable signs, the breath sounds over it being sometimes much diminished, at times frankly bronchial, and at others a patchy mixture of the two. The same range of signs was noted both where there were large woolly, partly confluent areas, and also where the consolidation was fully confluent and dense. For example, in one of the "primary atypical pneumonias" a comparable partly confluent consolidation in one lower lobe was associated with bronchial breath sounds and in the other lower lobe with very weak breath sounds.

Where there was marked percussion impairment the x-ray shadows were usually dense, but smaller shadows were found in resonant zones, particularly where emphysema had a masking effect. Many cases with chest pain showed pleural friction, and a number of these went on to develop pleural effusions, usually small, clear, and sterile. Pleural effusions always showed typical signs, but these at times suggested rather more fluid than was present—a not surprising fact when one remembered that in other cases consolidation mimicked the presence of fluid.

Two influenzal cases which developed staphylococcal abscesses in the consolidated areas showed clear cavernous breath sounds in the dull area near the cavitation. One non-influenzal case with an abscess cavity associated with little consolidation of the near-by lung showed the usual paucity of signs manifested by lung abscesses.

The slowness with which severe influenzal pneumonias cleared has been previously mentioned, and our cases were no exception. One extensive case took almost five months to become clear, and periods of two months from the outset were not uncommon. The heavy consolidations were naturally the most persistent; the "ground-glass" shadows usually cleared within three weeks, and the fine mottling even more rapidly.

Our findings accord with those of Ackermann (1941), who did not observe any specific form of influenzal consolidation. He found lobular consolidations, peribronchial consolidations, and "miliary" consolidations all in varying combinations. He also found that the appearances suggested pulmonary tuberculosis in some of his cases; but, apart from one case actually complicated by pulmonary tuberculosis and another with small upper-zone abscess cavities, this difficulty did not arise in our cases. The consolidations were usually in the lower zones, and as the shadows were of such varied character tuberculosis was not strongly suggested.

Bacteriology and Blood Examinations

Investigations of the sputum and blood are considered in the same section because a relationship between them might be expected. Scadding (1937) has mentioned that as a general rule his groups A and B (influenzal pharyngitis, tracheitis, laryngitis, and bronchitis) show neither significant organisms nor initial leucocytosis; and he believed that when leucocytosis occurs later in group B it is probably due to secondary infection. Similarly, he considered that in his group C the consolidations were due to secondary invaders which also caused leucocytosis, and in his "lobar" groups C3 and C4 pneumococci predominated in every case.

The question whether influenza or other respiratory viruses can alone cause consolidation is not fully decided. Goodpasture (1919) has described two cases of probable

are so apparent. Statistical departments can play an important and useful part in the planning and efficient management of the hospital service; but their credentials will fall into disrepute if they fail to advise caution in interpreting figures and translating them into administrative action without sufficient recognition of their limitations.

Survey of the Facilities for Treatment of Malignant Disease in the Birmingham Region

A survey was undertaken to assess the adequacy of existing facilities for the treatment of malignant disease, with particular reference to the provision of beds for radiotherapy. For this purpose a census of all patients in hospital on one day was taken. They were classified as: (a) suffering from malignant disease, in hospital for investigation on its account, and in hospital for non-malignant conditions; (b) occupying beds allocated to radiotherapy, beds specially reserved for malignant disease, and beds in general surgical, medical, or other wards. Tables V and VI show some of the results.

TABLE V.—Patients in Hospital on Account of Malignant Disease, November 1, 1950.

Patients Admitted for	No.	%
Radiotherapy	109	12
Radiotherapy combined with other treatment	53	6
Special medical or surgical treatment only	265	29
Nursing care (no special treatment)	251	28
Investigation	220	25
Total number	898	100

TABLE VI.—Treatment of Malignant Disease by Type of Hospital.

Type of Hospital	Total No. of Patients Admitted for Malignant Disease	Percentage of Patients Undergoing Various Treatments				Percentage of Patients Admitted for Investigation
		Rad. Ther. Alone	Combined R.T. and Other	Other	None	
A	340	28.8	7.4	35.3	3.5	25.0
1	56	—	—	45.0	23.0	32.0
2	124	2.4	7.2	30.0	22.5	37.0
3	28	—	—	35.5	39.5	25.0
4	168	1.0	9.0	30.0	37.0	23.0
5	40	—	—	—	72.0	28.0
6	106	2.0	2.0	8.5	79.0	8.5
7	2	—	100.0	—	—	—
9	22	13.5	—	36.5	45.5	4.5
14	1	—	—	100.0	—	—
15	11	9.0	—	36.5	18.0	36.5
Total	898	12.0	6.0	29.5	28.0	24.5

Note.—The types used in this table are the same as those shown in Table IV except that general hospitals of type 1 with a specific allocation of beds for radiotherapy have been classified separately as type A.

Of the confirmed cases, 38% were receiving surgical or medical treatment only, 36% were receiving no special treatment, 18% receiving radiotherapy only, and 8% were being treated by a combination of radiotherapy and surgical or medical measures. On the day of the census there were 172 patients receiving treatment involving radiotherapy. If we assume this number to be the daily average of beds occupied by such patients, the total number of beds required to be allocated to radiotherapy would be about 175.

In view of the fact that 28% of all patients in hospital on account of malignant disease were receiving no special treatment, their cases being presumably too far advanced for effective measures, it might be desirable to check the methods of cancer registration to ensure that such cases are included. Such cases are often seen initially in surgical out-patient departments and are later admitted

to hospital (particularly those of types 5 and 6) for nursing care in the terminal stages.

The census method used in this survey is a speedy and economical way of obtaining an overall picture of the hospital services in the region. But as it is a sample of the hospital population on one day only it may be attended with considerable error. This can be reduced somewhat by suitable selection of the census day—holidays such as Christmas Day, bank holidays, and so on must obviously be avoided. If necessary the census can be repeated in different seasons of the year. In this region it is used as a stop-gap method until the results of the hospital discharge study discussed below are available.

Hospital Discharge Study

Many hospitals in this region are co-operating in a regional hospital discharge study. For this, a small form suitable for punch-card analysis is completed for every patient discharged from hospital. Information relating to age, sex, place of residence, duration of stay in hospital, and diagnosis is collected by this means. The analysis of these cards will provide data for estimating the requisite allocation of beds on the basis of present-day needs. The relative age incidence of diseases necessitating hospital admission is of interest in the prediction of future requirements, which must conform to the needs of a population changing with respect to its age structure. The average duration of stay is of value in determining whether the existing allocation of beds among the specialties is satisfactory.

It should be recognized that differences found between hospitals do not necessarily indicate that one is more or is less efficient than the other. The diversity of work undertaken, special local conditions, and many other factors operate to produce numerical differences, which can, however, be used to point out the need for further investigation.

Estimation of Hospital Catchment Areas

Most general and some special types of hospital commonly serve an area, more or less constant in size but difficult to delimit. We may conveniently speak of such an area as the catchment area of the hospital. Prior to the appointed day municipally administered hospitals had catchment areas clearly defined by the boundaries of the local authority; and in most cases a residential qualification was necessary for admission; but this was not true of voluntary hospitals, which admitted patients irrespective of their home address.

The National Health Service does not recognize any residential qualifications for admission to hospital. Theoretically, a patient may be admitted to any hospital in the country, but in practice patients find it convenient to be admitted to the nearest hospital offering facilities appropriate to their need. Moreover, general practitioners in a district know the staff of their local hospitals and they, too, commonly refer their patients to these.

In determining the population served by a particular hospital the first requisite is a knowledge of the admissions to hospital by their place of residence. At the time when the population survey was made the discharge slips mentioned above were not in use and consequently recourse was had to a census method as a temporary expedient. This entailed the following assumptions:

(1) That the hospital population on the census day gives a representative sample of that on any other day in the year.

Needless to say, this assumption is not legitimate if a substantial proportion of beds are available for treatment of conditions subject to considerable seasonal variation.

(2) That within each local administrative area the density of population is uniform throughout. In urban areas no great errors are likely to arise from this assumption, while in rural areas the number of persons involved is so small that even if there are considerable variations—for example, concentration of population in small towns and villages—the error will not be large.

On October 19, 1949, a census was taken of all patients in every hospital in the Birmingham Region. Each hospital completed a form showing the number of patients by the administrative area of their home; the information was transferred to punch-cards. Special hospitals, including mental and mental deficiency hospitals, were considered separately.

There were 107 local government areas in the region for which official estimates of population were available. The cards were sorted out according to these areas. Thus for each area the number of residents in hospitals on that day was known, and also the names of hospitals to which they were admitted. In most areas these numbers give a good estimate of the total hospital population on that day. Estimates for areas at the boundaries would not be so accurate, as no information was available regarding persons resident in these areas but in hospitals outside the region.

The method of determining the catchment areas from these data is shown in Appendix A.

Nursing Staff Requirements

Valid comparison of staff/bed allocation in different hospital groups must take stock of the fact that the target varies from hospital to hospital, the mean allocation presumably deemed adequate for mental hospitals in particular being far below the general. In the Birmingham Region the composition of the groups with respect to different types of hospitals is highly variable, and therefore a low staff/bed ratio for a particular management group does not necessarily signify that it is understaffed. Crude rates such as the number of nurses per 100 beds may therefore be very misleading, and it is necessary to interpret them in juxtaposition to some yardsticks of adequacy. Differences in the staff situation in hospitals of diverse types are exemplified in Table III. The overall nurse/bed ratio for any particular type of hospital is the number of nurses per 100 available—that is, open and ready for use—beds.

The problem would be simple if we had firm figures for the requirements of each type of hospital. In the absence of such figures, the calibration of any yardstick of adequacy we adopt must rely on arbitrary assumption; and it is not unreasonable to suppose that the overall figures in the region as a whole for any particular type of hospital listed in Table III are not far short of requirements. In any case, it is instructive to present the relevant information in such a way as to answer the question: "Does the staffing of the hospital exceed or fall short of the overall standard for the region as a whole?" The crude rate as defined above does not answer this question, but we can make an answer explicit by recourse to a Regional Standard Index (R.S.I.) which has the value 100 if the staff situation in the group is equivalent to that in the region as a whole. A value greater than 100 signifies that the current staff allocation is above, and a value less than 100 that it is below, the regional standard so defined. The method of compu-

tation of the R.S.I. is shown in detail in Appendix B. It involves the application of a simple standardization procedure (similar to that for age standardization in vital statistics) to the nurse/bed ratios of different hospital groups.

Summary

The role of statistics in the National Health Service is discussed.

Variations in the hospital needs of different localities are discussed and some estimates of the number of beds required for each 1,000 persons are shown.

The administrative uses of statistics are illustrated by reference to a survey on the hospital treatment of patients with malignant disease.

Future developments in the statistical service of the Birmingham Regional Hospital Board are outlined.

A method of obtaining the population of hospital catchment areas is given.

The use of standardization in administrative statistics is discussed, and an example is given of its use in making comparisons of staff/bed ratios between hospital management groups.

While it is a pleasure to acknowledge the assistance given to me in this work by the Birmingham Regional Hospital Board and its officers, it is necessary to point out that the views expressed are personal and should not therefore be attributed to that Board or any members thereof. I gladly acknowledge the guidance and encouragement which I have received at all times from Professor Lancelot Hogben, F.R.S., without which none of this work could have been done.

APPENDIX A

Determination of Population of Hospital Catchment Areas

Let the total number of residents of area *A* who were in hospital on the census day be *a*; the number in *B* be *b*, etc. The total number of patients in regional hospitals on that day was (*a* + *b* + . . . + *r* + . . . + *x*).

In Hospital 1 there were *a*₁ patients from *A*, *b*₁ patients from *B*, *r*₁ patients from *R*, etc.

In Hospital 2 there were similarly *a*₂, *b*₂ . . . *r*₂, etc., patients from *A*, *B*, etc.

The proportion of in-patients from area *A* in Hospital 1 is

$$\frac{a_1}{a_1 + a_2 + \dots + a_x} = \frac{a_1}{a}$$

In most instances where area *A* is close to Hospital 1, *a*₁ is very nearly equal to *a*.

Let the total population of *A* be *n*_a, of *B* be *n*_b, etc. Then the population of *A* served by Hospital 1 is:

$$\begin{aligned} \frac{a_1}{a} \cdot n_a, \text{ by Hospital 2 is } \frac{a_2}{a} \cdot n_a, \text{ etc., and} \\ n_a = a_1 \cdot n_a \div a + a_2 \cdot n_a \div a + \dots + a_r \cdot n_a \div a \\ = \frac{n_a}{a} [a_1 + a_2 + \dots + a_r + \dots + a_x] \\ = \frac{n_a}{a} \sum_{r=1}^{r=x} a_r \end{aligned}$$

The population of *B* served by Hospital 1 is *b*₁ . *n*_b ÷ *b* and of *C* is *c*₁ . *n*_c ÷ *c*, etc.

Therefore the total population served by Hospital 1 is $a_1 \cdot n_a \div a + b_1 \cdot n_b \div b + \dots + r_1 \cdot n_r \div r + \dots + x_1 \cdot n_x \div x$

The splitting-up of the population of an area is arbitrary, and where two or more hospitals are in juxtaposition it is more satisfactory to determine the catchment area for the group rather than the individual hospitals.

The estimates would be more satisfactory if they were based on hospital admissions over a period of time—say six months or a year. In this region, when the discharge slips are received from all hospitals further estimates of the catchment areas will be made on that basis. However, the census method is recommended as a speedy and economical technique when facilities are not available for a more detailed survey.

APPENDIX B

Calculation of Regional Standard Index

The rationale of the R.S.I. is as follows. The overall nurse/bed ratio in the region for any particular type of hospital listed in Table III is obtained thus: if R_n is the total number of nurses employed and R_b the total number of available—that is, beds open and ready for use—beds in any one type, then the overall staff/bed ratio in the region for that type of hospital is $100 R_n \div R_b$. The overall ratios for June 30, 1949, are shown in Table III.

For each type of hospital in Table III we have the overall nurse/bed ratio, which may be denoted thus: $n_1, n_2, \dots, n_{12}$. For any particular management group our returns cite $b_1, b_2, \dots, b_{12}$ beds in one or other type of hospital, and $N_1, N_2, \dots, N_{12}$ nurses. If the staff situation tallies with that of the region there would be $n_x \cdot b_x \div 100$ nurses in the x th type of hospital, and the total (standard) number of nurses would be:

$$N_s = \frac{1}{100} (n_1 b_1 + n_2 b_2 + n_3 b_3 + \dots + n_{12} b_{12})$$

Actually it is

$$N_t = N_1 + N_2 + N_3 + \dots + N_{12}$$

If N_t exceeds N_s the hospital allocation is above par, and if N_t falls short of N_s it is below par. We may use $N_t \div N_s$ expressed as a percentage to convey this information. Thus we define the Regional Standard Index as:

$$\text{R.S.I.} = 100 N_t \div N_s$$

Computation of Regional Standard Index

In the Tables below two part-time nurses are counted as equivalent to one full-time nurse.

Type of Hospital	Overall Ratio for that Type (100 n_x)	No. of Available Beds	Estimated No. of Nurses Required $n_x \cdot b_x \div 100$	Actual No. of Nurses Employed N_x
Hospital Management Committee A				
5. General	47.8	235	112	119.5
12. Tuberculosis and fever	33.6	59	20	25.5
7. Maternity	14.7	22	3	7.0
3. Cottage	41.0	9	4	4.0
3. Cottage	41.0	10	4	3.5
6. Mental	13.3	1,183	157	189.5
1. Chronic sick	23.1	290	67	48.5
Total		$B_t = 1,808$	$N_s = 367$	$N_t = 397.5$
Hospital Management Committee B				
5. General	47.8	159	77	80.0
5. General	47.8	287	136	120.0
1. Chronic sick	23.1	176	41	40.5
7. Maternity	14.7	14	2	5.0
11. Tuberculosis	20.4	19	4	10.0
4. Isolation	28.5	12	3	2.0
11. Tuberculosis	20.4	22	4	4.5
Total		$B_t = 689$	$N_s = 267$	$N_t = 262.0$

$$\text{Crude rates} = 100 N_t \div B_t$$

$$\text{Regional Standard Index} = 100 N_t \div N_s$$

	H.M.C. (A)	H.M.C. (B)
Crude rate	$\frac{100 \times 397.5}{1,808} = 22$	$\frac{100 \times 262}{689} = 38.8$
R.S.I.	$\frac{100 \times 397.5}{367} = 108$	$\frac{100 \times 262}{267} = 98$

Thus from the crude rates it would appear that B has almost twice as many nurses as A, but when due allowance is taken for the differences in composition of the groups A is somewhat higher and B lower than the regional average.

PRIMARY TUBERCULOUS PLEURAL EFFUSION IN OLDER AGE GROUPS

BY

R. F. ROBERTSON, M.B., M.R.C.P., M.R.C.P.Ed.

Senior Medical Registrar, Royal Infirmary, Edinburgh

The primary serous pleural effusion in children and young adults no longer presents an aetiological problem. Many series of cases, carefully investigated and laboriously followed up, have been reported in the literature, leaving no doubt that, with few exceptions, the tubercle bacillus, although seldom declaring its presence in the fluid, is lurking in the background, prepared in later years to exact a further toll on the health of the victim.

A similar effusion in adults over 40 years of age presents a much greater problem in diagnosis, because of the lessening incidence of tuberculosis and the increasing incidence of malignant disease. From the statistical point of view it is clear that, unless care is taken at the outset to exclude malignant cases from consideration, morbidity and mortality occurring during a follow-up period, especially if the investigator is dependent on a postal questionnaire without necropsy control, may be wrongly attributed to tuberculosis. It is of interest in this connexion that Fauvet (1945), as a result of a follow-up of 731 cases of serous pleural effusion, believes that tuberculosis morbidity and mortality increase with advancing years. On the other hand, Maclean (1948) fears that such a deduction may be erroneous, and that it is almost certainly due to the inclusion of a number of cases in which malignant disease is the real cause. The *British Medical Journal* (1946) points out that the prognosis with respect to the development of tuberculosis is much better in children than in young adults, but does not venture an opinion on adults over 40, in whom it states that "carcinoma of the lung is common."

Another statistical error may occur in all age groups, but more so in the older groups, if cases with the adult type of pulmonary tuberculosis complicated by effusion are included. As Thompson (1947) has pointed out, the prognosis in this type of case is that of pulmonary tuberculosis in general, and is therefore much worse than that of effusion occurring in the period after a primary infection. Radiology may fail to reveal an adult type of lesion until considerable absorption of the effusion has taken place; such a case may be wrongly included as a primary effusion.

The present investigation was undertaken to determine the frequency and prognosis of primary tuberculous pleural effusion in patients over 40. Case material was selected from admissions to five medical charges in the Royal Infirmary of Edinburgh during a period of five years, from 1945 to 1949. All patients aged over 40 found on admission to have a serous pleural effusion of uncertain aetiology were included initially in the investigation, and total 60 in number. Cases in which the pleural effusion was secondary to some obvious lesion in the lungs, heart, or elsewhere were excluded (except those in which the lung lesion was suggestive of the adult form of pulmonary tuberculosis). Two of the 60 patients selected left hospital against advice before investigations could be completed, and were therefore omitted from the final analysis. The remaining 58 were carefully investigated, and the follow-up is complete. Table I shows the ultimate diagnosis in these cases.

TABLE I.—*Ultimate Diagnosis in 58 Cases of Pleural Effusion of Uncertain Aetiology occurring in Adults over 40*

Diagnosis	No. of Cases
Bronchial carcinoma	11
Tumours other than bronchial carcinoma	8
Simple inflammatory	7
Collagen disease	4
Cardiac transudate	2
Reticulosis	2
Pulmonary infarction	1
Adult pulmonary tuberculosis	2
Uncertain	1
Primary tuberculosis	20
Total	58

Comments on Diagnosis

Bronchial Carcinoma

Of the 11 cases, 1 was confirmed by necropsy, 2 by bronchoscopic biopsy, 1 by thoracoscopic biopsy, and 2 by the later development of unequivocal radiological signs; the remaining 5 were less certainly confirmed by the development of probable radiological signs and/or a rapid downhill clinical course with recurrence of massive blood-stained effusion and a fatal termination.

Tumours Other than Bronchial Carcinoma

Of the 8 cases, 4 were confirmed by necropsy, 1 by the development of undoubted (radiological) secondaries in the lungs, and 3 by the finding of malignant cells in the fluid associated with clinical or radiological evidence of a primary tumour elsewhere in the body.

Simple Inflammatory Cases

All 7 cases had been treated with a sulphonamide and/or penicillin before admission and had clear sterile effusions without definite radiological evidence of lung consolidation; 5 were regarded initially as possible tuberculous effusions, 1 as a possible malignant effusion (Case 6), and 1 as a possible simple inflammatory effusion (Case 7). Four cases had a predominance of polymorph neutrophils in the exudate, 1 a predominance of polymorph eosinophils, and 2 a predominance of ordinary lymphocytes. The subsequent course of events in each case was as follows:

Case 1.—Initial pyrexia subsided with further sulphonamide and penicillin, but subsequently became hectic, with leucocytosis; eventual cure occurred with the coughing up of a large quantity of pus, suggestive of pulmonary or pleuro-pulmonary abscess.

Case 2.—Pyrexia and fluid persisted. After discharge to a convalescent home the patient developed purulent sputum (negative for tubercle bacilli) and finger clubbing; subsequent investigation revealed a bronchiectatic lower lobe on

the side of the effusion. The lobe was resected at thoracotomy, which revealed no evidence of tumour or tuberculosis; the original effusion was lymphocytic.

Case 3.—Pyrexia persisted and originally clear effusion became turbid; subsequent resection of empyema space showed no pathological evidence of tuberculosis.

Case 4.—Pyrexia subsided rapidly with further sulphonamide and penicillin. While convalescent the patient had a brisk haemoptysis. A radiological follow-up for four years showed gradual development of bilateral bronchiectatic changes.

Case 5.—Pyrexia had subsided before admission. Effusion contained 50% eosinophils. The Mantoux test (1:100) was negative, and has remained so during repeated tests over two years.

Case 6.—Pyrexia responded to further penicillin and sulphonamide; a subsequent relapse also responded. First aspiration—lymphocytes; second aspiration—lymphocytes plus possible malignant cells. The diagnosis of malignant disease was strengthened by the finding of a mass attached to the liver, but the patient was alive and well two years later. The mass is now thought to be an abnormal lobe of the liver. The condition is regarded as a simple inflammatory one because of the undoubted response on two occasions to sulphonamide and penicillin.

Case 7.—In addition to pyrexia and left pleural effusion, the patient had hypertension and auricular fibrillation, but there was no evidence of either left- or right-sided cardiac failure. The effusion was clear and sterile, but with polymorph exudate. Pyrexia responded slowly to penicillin and sulphonamide; the effusion cleared up, but localized coarse crepitations appeared and persisted in the left lower lobe, indicating resolving consolidation (not visible on x-ray film). The patient died of congestive cardiac failure some months after discharge.

Collagen Disease

Of the 4 cases, 1 presented with a bilateral pleurisy which went on to bilateral effusion with high temperature. The provisional diagnosis was miliary tuberculosis, but necropsy showed unequivocal evidence of disseminated lupus erythematosus. The remaining 3 cases presented with vague muscular pains, including chest pain, which was at first thought to be muscular in origin; all, however, developed bilateral effusion associated with a long-continued toxic illness, and eventually showed changes in the hands diagnostic of rheumatoid arthritis; 1 of the 3 cases had a predominance of eosinophils in the pleural fluid. Although it is impossible to exclude tuberculosis in those cases, it is regarded as important that in each case the fluid was bilateral and was associated with subsequent undoubted evidence of a disease known to involve diffusely all the fibrous tissues in the body. Bilateral effusion in tuberculosis is uncommon. Necropsy studies of cases of rheumatoid arthritis have shown that pleural fibrosis without evidence of tuberculosis, either past or present, is a common finding (Rosenberg, Baggenstoss, and Hench, 1944; Fingerman and Andrus, 1943).

Cardiac Transudate

Of the 2 cases, 1 presented with slight dyspnoea and was found to have a left-sided pleural effusion. Neoplasm and tuberculosis were being considered, when the patient died suddenly. At necropsy an unsuspected cardiac infarct, approximately three weeks old, was seen to involve the left ventricle. There was no evidence of neoplasm, tuberculosis, or lung infarct. The right pleural cavity was completely obliterated by old adhesions, thus accounting for the strictly unilateral nature of the

transudate. The other case has been reported previously (Robertson, 1951); this patient presented with a puzzling interlobar effusion which eventually proved to be cardiac in origin.

Reticulosis

One case presented with a right pleural effusion which was thought to be tuberculous in origin. Some months later signs of superior mediastinal obstruction and generalized lymphadenopathy developed: a gland biopsy showed a lymphoid follicular reticulosis, in which serous effusion is a common finding (Hadfield and Garrod, 1947). The other case was known to have a reticulosis of obscure type, gland biopsy suggesting the possibility of atypical Hodgkin's disease. Bilateral pleural effusion developed in the absence of radiological evidence of thoracic gland involvement. In view of the possible confusion pathologically between Hodgkin's disease and tuberculosis, the latter was considered in diagnosis. The effusions, however, proved to have a low protein content; this led to estimation of the plasma proteins, when the albumin was found to be 2.29 g.%. A high protein diet corrected the low plasma albumin, and the pleural fluid disappeared. It seems reasonable to conclude that the pleural effusions were transudates due to hypoproteinaemia complicating a reticulosis.

Pulmonary Infarction

This patient was in a hospital ward for investigation of gall-bladder disease. While in bed she developed an acute pleurisy, with subsequent rapid development of a clear serous effusion; there was no evidence of pneumonia. Haemoptysis appeared on the third day of illness. A pulmonary infarction seems the most probable diagnosis in view of the haemoptysis and the onset of illness while in bed; there was, however, no evidence of thrombophlebitis, and tuberculosis had been considered prior to the haemoptysis.

Adult Pulmonary Tuberculosis

Two cases had radiological changes in the lungs suggestive of this condition: in both, the sputum was found to contain tubercle bacilli. It should be noted that the number in this group is artificially small, as such cases are not admitted to the Royal Infirmary of Edinburgh if alternative accommodation can be obtained.

Uncertain

This patient, known to have hypertension, was resting in bed at home. She developed a febrile illness with pleuritic pain and copious purulent sputum, and a clear serous lymphocyte effusion subsequently occurred. All investigations for tuberculosis were negative. A follow-up for four years showed recurrent bronchitis, asthma, obesity, and hypertension. As the main illness took place at home and she was seen only when the effusion was clearing up, it is difficult to suggest a diagnosis: "simple inflammatory" seems a more probable diagnosis than tuberculosis.

Primary Tuberculosis

Of the original 58 cases 38 have been described above, leaving 20 in which a diagnosis of primary tuberculosis was made. It should not be thought, however, that this diagnosis rests entirely on a process of exclusion. Of these 20 cases 14 had an illness resembling in every respect the classical primary tuberculous effusion in the young adult—that is, sudden onset, in a previously healthy person, of acute pleuritic pain progressing to a clear serous lymphocytic effusion, with no radiological

evidence of lung disease, and pursuing a protracted febrile course unresponsive to chemotherapy and antibiotics. Five others of the 20 had a similar illness, but the onset was more insidious, and there was little or no pleuritic pain. The remaining case had an acute pleurisy progressing to effusion, without pyrexia at any time. In only two cases was the tubercle bacillus isolated from the pleural fluid; this does not invalidate the diagnosis, since in similar cases in young adults it is notoriously difficult to isolate the bacillus unless special methods are used. No case had tubercle bacilli in the sputum or gastric washings. X-ray films of the chest after clearing of the effusion did not reveal any case of adult pulmonary tuberculosis. Follow-up has excluded any disease, other than tuberculosis, which might have accounted for a pleural effusion.

Discussion

In this series of 58 cases of serous pleural effusion of initially uncertain aetiology occurring in adults over 40 years of age, only 20 could be ascribed to primary tuberculous infection. Nineteen proved to be secondary to malignant disease of the lungs or elsewhere. Only two were due to the adult form of pulmonary tuberculosis, but this is an artificially small number because of the restricted admission of this type of case to a general hospital. Details of the remaining 17 cases have been included to justify their grouping under miscellaneous conditions given in Table I.

As stated earlier, this series of cases was selected from admissions to five medical charges during a period of five years from 1945 to 1949. In order to find the relative frequency of primary tuberculous effusion in adults over 40, the corresponding numbers of cases of primary tuberculous effusion in children and young adults admitted to the same five charges over the same period of time were determined. The details are given in Table II. It was found that almost 10% of primary tuberculous effusions occur in adults aged over 40.

TABLE II.—Age Distribution of 216 Cases of Primary Tuberculous Pleural Effusion Occurring over a Five-year Period

Age (Years)	No. of Cases	%
Under 20	117	54.1
20-29	60	27.8
30-39	19	8.8
40-49	12	5.5
50-59	3	1.4
60-69	4	1.9
70-79	1	0.5
Total	216	100

It is difficult to estimate how many people in Great Britain over 40 are tuberculin-negative. Recent tuberculin surveys have concerned children and young adults, but in 1934 Kayne found that among non-tuberculous admissions to a general hospital in London 15% of the 45-59 age group and 14% of the over-60 age group were tuberculin-negative. Those figures are probably artificially high, as it is well known that debility and intercurrent illness in hospital patients may inhibit the tuberculin reaction. In a recent paper from Norway, Jonsen and Ustvedt (1950), using a combination of Mantoux and B.C.G. tests, conclude that lack of tuberculous allergy in old people is not so common as has been assumed, being in the region of 12%.

While there may be some doubt about the precise number of older people liable to acquire a primary

infection, Terplan (1940) and Pagel (1948), in their pathological studies, have proved beyond question that primary infection does occur. Terplan in addition has shown that an older person may acquire a "second" primary infection when the "first" primary infection has become completely inactive (presumably with reversion to tuberculin negativity). Kayne, Pagel, and O'Shaughnessy (1948) believe, further, that an old primary infection may commonly flare up in people over 45 years. It would seem, therefore, that a primary tuberculous effusion may occur in older people following delayed primary infection, reactivation of old primary infection, or "second" primary infection.

In the present series of 20 cases, one case which came to necropsy showed reactivation of a primary Ghon focus. Most of the 20 had lived in large cities since early childhood and therefore had every opportunity of acquiring infection earlier in life. No case had a history of recent contact with a known source of infection. Only one case showed radiological evidence of hilar gland enlargement, this being the only point in which the clinical picture differed from that of similar effusions in children and young adults, in whom such radiological evidence is much more common. This difference has been noted previously (Landau, 1949), and may mean that in the older person a typical primary complex, in which hilar gland enlargement is usually marked, is not commonly present. It is not possible to draw definite conclusions from this series of cases, but it would seem that delayed primary infection, in its typical form, is probably not an aetiological factor.

While it has been proved (Graham, 1925; Smithers, 1934; Vaizey and Perry, 1940; Landau, 1949) that primary tuberculous effusion in children has a surprisingly good prognosis, there is little agreement in the literature concerning the influence of advancing years. Thompson (1946), whose series of 233 cases included only 13 over 40 years of age, considers that age *per se* does not matter with respect to the development of tuberculous lesions. On the other hand, Fauvet (1945), Gaarde (1930), and Farber (1943) show that in those over 40 years of age the prognosis tends to become worse. It is unfortunate that many series in the literature include no cases older than 40, and that those which do have, of necessity, all too few for statistical purposes. The old enemies, inadequate follow-up and doubtful diagnosis, also play a part in invalidating statistics.

Unfortunately, the present series of 20 cases over 40 years of age is also small, but efforts have been made to eliminate errors in diagnosis, and follow-up over a period of three to six years is complete. All surviving cases have been examined clinically and radiologically, and necropsy has been performed on those who died. Table III indicates that the incidence of tuberculous morbidity is 45%, with a corresponding mortality.

TABLE III.—Follow-up of 20 Cases of Primary Tuberculous Pleural Effusion in "over 40" Age Group

	No. of Cases
Alive and well	11
Dead—Pulmonary tuberculosis	2
—miliary	1
—pericardial	1
Alive—active pulmonary tuberculosis	3
—inactive	1
—recurrence of effusion on other side	1

Although no sweeping deductions can be made from this small series, it is clear that the primary tuberculous effusion is a potentially serious disease in older people. The morbidity figure of 45% compares unfavourably with the average morbidity of 14% calculated from nine

series of cases of primary effusion, mostly in younger age groups, published between 1945 and 1949. That its potential gravity is perhaps not fully appreciated, is illustrated by the fact that only 9 of the 20 cases received a period of treatment at a convalescent home, before being returned to normal life; and in only 3 was that period longer than one month (it so happens that those 3 are alive and well). It may be that the bad prognosis in this series is partly due to this factor. In comparison, virtually all children and young adults with effusion have a prolonged period of convalescence. It would seem that efforts should be made to secure adequate convalescence for all cases of effusion, irrespective of age.

Summary

An investigation is presented in which an attempt has been made to elucidate problems relating to the frequency and prognosis of primary tuberculous pleural effusion in the older age groups.

In a series of cases in adults over 40 years of age presenting with a serous pleural effusion, approximately one-third proved to have a primary tuberculous effusion; in the remainder the effusion proved to be secondary to some other condition.

Approximately 10% of all primary tuberculous pleural effusions occur in adults over 40.

The aetiology of primary tuberculous pleural effusion in older age groups is discussed in relation to delayed primary infection, reactivation of an old primary infection, and a "second" primary infection. No definite conclusion is reached, but delayed primary infection seems an unlikely aetiological factor.

Difficulties in assessing the prognosis of primary tuberculous pleural effusion in the older age groups are discussed. The present investigation suggests that subsequent tuberculous morbidity is greater in them than in children and young adults.

The early part of this investigation was carried out with the help of a grant from the Royal Victoria Hospital Tuberculosis Trust. I am greatly indebted to the physicians of the Royal Infirmary of Edinburgh who allowed me access to their cases and case records. I wish to thank Professor Charles Cameron for his kindly criticism.

The use of blood has increased more than twofold since the beginning of 1946. Part of this increase may well be fully justified, but there is probably also avoidable waste. Continuous supervision of blood banks is essential: an average blood bank may be said to be running economically and efficiently if not more than 10 to 15% of the blood issued to it by the Regional Transfusion Centre is returned unused, and if this is fit for conversion to plasma. The Ministry of Health has issued suggestions on how this can be achieved.

RADIOLOGICAL CHANGES IN THE SKULL IN DYSTROPHIA MYOTONICA

BY

J. E. CAUGHEY, M.D., F.R.C.P., F.R.A.C.P.

Physician to the Auckland Hospital, N.Z.

In a previous endocrine study of dystrophia myotonica Caughey and Brown (1951) made reference to certain radiological abnormalities of the skull in dystrophia myotonica, and suggested that these changes should be regarded as variable features of the disorder. Since that time I have had the opportunity of studying further cases which have presented with similar radiological findings. No mention of these findings has been discovered in the standard textbooks, and this additional account is recorded in the hope that it may stimulate interest and establish the clinical significance of these changes by radiological study of many more cases than one observer can hope to collect.

Historical

Myotonia was first described by Leyden in 1874. In 1876 Thomsen, who himself suffered from myotonia, recorded his own symptoms and signs. The combination of myotonia and muscle atrophy was described by Dana in 1888, but it is Déléage (1890) who is usually credited with the first account of dystrophia myotonica. In 1909 Steinert wrote a full description of the disease, and first described changes in the mental state and some of the associated dystrophic features such as premature frontal baldness and gonadal atrophy. At the time, these latter findings were regarded as being merely coincidental. In 1911 Greenfield recorded the constant association of cataract in the disorder, and thereafter the other dystrophic manifestations of the disorder came to be recognized as an essential part of the clinical picture in the fully developed disorder of the "dystrophic" generation.

Few authors have made reference to radiological changes in the skull in these patients. Scharnke and Full (1920) described a large frontal sinus in the presence of a normal pituitary fossa. Rouquès (1931) reported the radiological findings of the skull in four patients. The calvarium was distinctly thickened in three and less so in the fourth. Large frontal sinuses occurred in two, in two the pituitary fossa was small, and in two it was bridged over by an area of calcification. Fagin (1946) reported the occurrence of hyperostosis frontalis in two patients.

Clinical Reports

This study is based on 13 patients with dystrophia myotonica—all members of the so-called "dystrophic generation" and all presenting myotonia, characteristic muscle-wasting, and various dystrophic lesions such as cataract, gonadal atrophy, and frontal baldness. It is considered that in none of these cases can there be any reasonable doubt about the diagnosis. Most of them have been reported in detail elsewhere, and are here recorded in brief but with full radiological reports.

Case 1.—A farmer aged 45, single, developed weakness and wasting of the arms and legs and myotonia at the age of 27. The weakness progressed until he became almost bedridden. Soon after the onset of the disease he developed bilateral cataract, premature frontal baldness, and gonadal

atrophy. Post-mortem findings confirmed the diagnosis of dystrophia myotonica, with the disorder fully developed. **Radiological findings:**—Skull (Fig. 1): the vault shape was normal; the calvarium was thickened; hyperostosis interna frontalis et parietalis was present; the sinuses were within normal limits; the mandible was normal; the pituitary fossa was small, with a pneumatized dorsum sella; the pineal body was calcified.

Case 2.—A single panel-beater aged 26 presented with auricular flutter in 1945. Myotonia had been noted two years prior to this. He had the fully developed disease, with myotonia, wasting of the face, arms, legs, and sterno-mastoid muscles. There was no gonadal atrophy and no cataract. **Radiological findings:**—Skull: the vault shape was normal and the calvarium thickened, especially in the posterior parietal region; there was a hyperostosis interna frontalis; the frontal sinuses were deep; the sphenoidal sinus was large and the pituitary fossa very small.

Case 3.—A married woman aged 33 developed myotonia at 21. Wasting and weakness of legs, arms, face, and neck

Fig. 1.—Case 1. Calvarium thickened; hyperostosis interna; pituitary fossa small.

muscles were apparent at 28, and bilateral cataract developed at 30. **Radiological findings:**—Skull: the vault shape was normal and the calvarium thickened throughout, with moderate hyperostosis interna frontalis et parietalis; the sphenoidal sinus was large and other sinuses were within normal limits; there was pneumatization of the dorsum sella; the pituitary fossa was small, and the pineal body was calcified.

Case 4.—A male factory-hand aged 27 had for two years noted myotonia, weakness of the neck muscles, wasting of the forearms and legs, and frontal baldness. He presented with myotonia and characteristic muscle-wasting. There were no lenticular opacities, and no gonadal atrophy was noted. **Radiological findings:**—Skull: the calvarium was thickened and there was hyperostosis interna frontalis; the sinuses were normal in size; the pituitary fossa was small.

Case 5.—A military pensioner aged 32 first noted myotonia while a prisoner of war in Germany in 1942. In 1946 he presented with myotonia, wasting of sterno-mastoids, forearms, and legs. There was cataract and frontal baldness, but gonadal atrophy was not noted. **Radiological findings:**—Skull: the calvarium was normal; there was a very grossly calcified falx cerebri, which was responsible in part for the appearance of a nebula frontalis; no definite hyperostosis was present; the pituitary fossa was normal to small; all sinuses were large.

Case 6.—A carpenter aged 41 developed failure of potentia at 34. Myotonia was noticed four years later, and wasting

of face, neck, forearms, and legs became apparent. He presented a characteristic picture, with myotonia, muscle-wasting, and gonadal atrophy. *Radiological findings*:—Skull: there was no thickening of the calvarium; the frontal and sphenoidal sinuses were extensive and deep; the pituitary fossa was small; the dorsum sellae was completely pneumatized; the jaw was prognathous.

Case 7.—A housewife aged 51 had noticed weakness of her neck muscles since she was 30. The sterno-mastoid muscles had wasted, there was progressive wasting and weakness of her forearms and legs, and she had bilateral cataract. Mechanical myotonia was present. The ankle-jerks were absent. *Radiological findings*:—Skull: there was thickening of the whole calvarium with loss of differentiation of the cortex and the diploe and extensive hyperostosis interna frontalis. The sinuses were normal and the pituitary fossa was very small, with calcification near the floor. There was no pneumatization of the dorsum sellae.

Case 8.—A labourer aged 28, who had been backward at school, at 17 noticed difficulty in relaxing his grasp, and his arms and legs became progressively weaker and wasted. Visual deterioration had been apparent for five years. He presented with myotonia, muscle-wasting, bilateral lenticular opacities, and frontal baldness. The gonads were not obviously atrophic. *Radiological findings*:—Skull: the vault was normal in size and the calvarium was thickened; there was extensive hyperostosis interna frontalis et parietalis; the vertical component of the frontal sinus was normal, but the horizontal component extended almost to the anterior clinoids; the pituitary fossa was very small, and the dorsum sellae was thick and partially pneumatized.

Case 9.—A grocer aged 33, who was backward at school, first noticed myotonia at 13 years. Wasting of face, arms, and legs developed two years later. He presented with marked myotonia, wasting of sterno-mastoid muscles, and face, forearms, and legs. There was marked gonadal atrophy, but there were no cataracts. *Radiological findings*:—Skull (Fig. 2): the vault was small, globoid, and microcephalic; the calvarium was thickened but of normal density; the sinuses were extensive and deep, especially the sphenoids, which extended into the posterior clinoid processes; the pituitary fossa was very small and the jaw markedly prognathous.

FIG. 2.—Case 9. Calvarium thickened; pituitary fossa very small; jaw prognathous; sinuses extensive.

Case 10.—A spinster aged 45 had been admitted to a mental hospital nine years previously. Six years later she developed myotonia, and in 1950 presented with bilateral cataract, myotonia, and wasting of the face, sterno-mastoid muscles, forearms, and legs. *Radiological findings*:—Skull: there was marked hyperostosis interna frontalis; the floor of the anterior fossa was more vertical than usual and the pituitary fossa was small; the frontal sinus showed a large horizontal component and a very large vertical component; the sphenoidal sinus was large and the antra were normal; the jaw was prognathous.

Case 11.—A housewife aged 47 developed bilateral cataract nine years previously. When examined she presented myotonia of grasp and some weakness of the sterno-mastoid muscles. *Radiological findings*:—Skull: the calvarium was thickened; there was hyperostosis interna frontalis; the pituitary fossa was small and the sinuses were all normal.

Case 12.—A farmer aged 42 first noticed myotonia in 1941, and weakness and wasting of his arms and legs developed a year later. He presented with myotonia and wasting of the sterno-mastoid muscles, forearms, and legs. There was bilateral cataract, with frontal baldness, gonadal atrophy, and areflexia. *Radiological findings*:—Skull: the calvarium was normal; there was no hyperostosis; the pituitary fossa was small; the frontal sinuses were extensive and the sphenoidal sinus was large.

Case 13.—A spinster aged 42 had for 15 years noticed an inability to relax her grasp. For 15 months her legs had been weak and wasting had developed. On examination there was wasting of the face, forearms, and legs, and the sterno-mastoid muscles had wasted completely. There was myotonia of grasp. *Radiological findings*:—Skull: there was marked thickening of the calvarium, the average thickening being approximately 1.5 cm. This thickness was evenly distributed and involved all the bones of the vault. There was also evidence of some hyperostosis interna frontalis. The pituitary fossa was also abnormally small. Both anterior and posterior clinoid processes and the dorsum sellae were well developed.

Discussion

These 13 patients all suffered from dystrophia myotonica and all were members of the so-called "dystrophic generation." It is realized that in assessing the size of the pituitary fossa and the size of the sinuses in the standard views the radiologist bases his opinion largely on subjective impression, as strictly accurate measurement is not always possible.

In the above reports the size of the pituitary fossa is classified as normal, small, or very small—"small" indicating a sagittal diameter below 9 mm. and/or a vertical diameter below 6 mm.; "very small" indicating measurements below 6 mm. and/or 4 mm. respectively for the same diameters. With two exceptions the magnification distortion was known to be the same in all cases.

The pituitary fossa was small in seven cases, normal to small in one, and very small in five. Thickening of the calvarium occurred in nine cases. The next most constant finding was the presence of hyperostosis interna frontalis et parietalis, which was noted in nine and was pronounced in three of these. It is notable that five of these cases were males aged from 26 to 45 years. Enlargement of the sinuses was noted in eight, and in two the mandible was elongated.

In view of these findings it seems evident that these radiological abnormalities of the skull must come to be accepted as one of the variable dystrophic features of dystrophia myotonica.

Summary

Thirteen cases of dystrophia myotonica are reported in brief. All presented some radiological abnormalities of the skull. The most constant changes were a small to very small pituitary fossa, thickening of the calvarium, and hyperostosis interna. There was enlargement of the sinuses in some and in two the mandible was elongated. We believe the high incidence of these changes cannot be coincidental, and it is held they should now come to be accepted as some of the variable features of dystrophia myotonica.

It is a pleasure to thank various physicians who have given me access to their cases, and Dr. Alexander and Dr. Rolleston for reviewing the radiological reports.

BULLOUS LESIONS IN LEUKAEMIA

BY

RONALD SCUTT, M.B., M.R.C.P.Ed.

Late Senior Dermatological Registrar, Norfolk and Norwich Hospital

The skin manifestations of leukaemia are many and varied: Arzt and Fuhs (1929) have mentioned eczematous, erythema-multiforme-like, purpuric, zosteriform, urticarial, bullous, and rupial lesions, in addition to exfoliative erythrodermia and the specific leukaemic deposits occurring in the form of small papules, nodules, or large tumours.

Wiener (1947) states that bullous eruptions may precede generalized exfoliative erythrodermia in lymphatic leukaemia, and that they are often encountered in the early stages of monocytic leukaemia. It would seem that remarkably few cases of leukaemia with bullous lesions have, in fact, been recorded. In an analysis of a series of 445 cases of the reticuloses (including 160 cases of leukaemia) at the Los Angeles County Hospital, Epstein and MacEachern (1937) reported cutaneous involvement in 194 (43.5%). Bullous or vesicular lesions were seen in six cases, of which three were Hodgkin's disease, two myeloid leukaemia, and one lymphosarcoma. No bullous eruption was seen in any cases of lymphatic, monocytic, or acute leukaemia.

Margarot, Rimbaud, and Roche (1935) reported the case of a boy of 12 years, who was first seen with a purulent bullous eruption on the lower limbs, associated with pyrexial attacks. It was only when, five months later, he developed a generalized erythrodermia associated with palpable lymph nodes that a blood count revealed a leucocytosis of 34,000 per c.mm., of which 91% were primitive cells of the lymphatic series. The diagnosis of acute leukaemia was confirmed by the subsequent course of the disease, with the development of ulcerative stomatitis and a severe bleeding tendency, and death within four months of establishment of the diagnosis.

Remenovsky (1935) described the case of a 51-year-old patient with an acute leukaemia (leucocytes 83,600 per c.mm., 91.7% immature lymphocytes). After systemic arsenic the blood picture changed dramatically, the total leucocyte count falling to 6,000 per c.mm., 40% being lymphocytes. At the same time bullous eruptions developed on the wrists and forearms.

It would seem that the few recorded cases of bullous dermatoses have been associated with acute leukaemia. The following case of chronic lymphatic leukaemia is therefore of particular interest because of several unusual features: the manner of presentation as a bullous eruption on the palms and soles; the remarkable bluish infiltrated erythematous eruption on the face; and the presence of four other skin manifestations—namely, purpura, erythema-multiforme-like lesions, cellulitis, and the specific papular infiltrate.

Case Report

The patient, a married woman aged 65, first reported to the skin clinic at the Norfolk and Norwich Hospital on July 26, 1950. She gave a history of a bullous eruption which started one month previously on the right sole, later involving the left sole and the left palm. She had had a sore throat at the onset. There was no relevant previous history.

On examination bullae up to 1 cm. or more in diameter were scattered over the soles of both feet. The dorsa of the feet and webs of the toes were quite normal. There were a few confluent bullae on the left thenar eminence. All lesions contained clear fluid at this stage. General examination revealed no abnormalities. Scrapings taken from the feet showed no evidence of fungus infection.

In the absence of a history of possible contact irritants, it was thought that the eruption was in the nature of a bullous pompholyx, and treatment was given in the form of baths of potassium permanganate, and phenobarbitone, $\frac{1}{2}$ gr. (32 mg.) thrice daily. The local treatment was changed after a week to Castellani's paint, and later to 0.5% gentian violet. No progress was made, and after a month both palms were severely involved.

In view of the discomfort and the lack of response to treatment, the patient was admitted on October 4. By this time bullae had begun to appear on the dorsa of both feet, and some haemorrhagic elements were present (Figs. 1 and 2). Glands were palpable in both axillae and groins, but the spleen was not felt.

A blood examination on October 11 showed a total leucocyte count of 79,800 per c.mm., of which 91% were lymphocytes. On November 3 her leucocytes had gone up to 123,200 per c.mm., of which 90% were lymphocytes, 4% monocytes, and 6% polymorphs. (Her haemoglobin at this stage was 98%.) No primitive cells were seen. Large numbers of smear cells were present in stained films. The platelets were not accurately estimated at the time, but the impression was that they were reduced. A sternal marrow examination on November 15 confirmed the picture of chronic lymphatic leukaemia.

A course of superficial x rays (to a total of 450 r) produced a dramatic effect on the bullae. After four weeks the hands were completely normal again and there were only a few small lesions on the dorsa of the feet.

During the period in hospital she developed cellulitis of the legs; this responded rapidly to penicillin.

One week before discharge on November 24 a few scattered pinhead-sized erythematous papules had developed on the anterior surfaces of the knees and thighs. When she was seen in the out-patient department on December 7 the hands were still normal but new purulent bullae had appeared on the soles. Both feet showed a diffuse erythema

FIG. 1.—The dark pigment is not due to haemorrhage but is gentian violet.

FIG. 2.—Showing the bullous lesions that developed later on the dorsa of the feet in addition to the soles.

and both legs were oedematous and very tender as far up as the knees. Large glands were palpable in both groins. It was considered that the oedema was partly inflammatory and partly due to pressure by glands on the deep veins. A few bluish infiltrated nodules were present around the right nipple, and some pinhead-sized erythematous papules over the upper part of the sternum; there was also a diffuse erythema of the forehead. The spleen was palpable 3 in. (7.5 cm.) and the liver 1 in. (2.5 cm.) below the costal margin. A radiograph of the chest revealed the presence of mediastinal glands.

A blood count on December 7 showed: haemoglobin, 82%; leucocytes, 169,000 per c.mm. (lymphocytes 95%, monocytes 1%, polymorphs 4%).

It was decided to irradiate the glands in the axillae, groins, and mediastinum.

Progress

December 20.—The oedema of the legs had increased, and many punctate purpuric lesions were seen, especially over the shins. The most striking feature was the indurated erythema of the face, which had now spread on to the cheeks; x-ray treatment was prescribed for this. The leucocytes numbered 160,000 per c.mm.

January 16, 1951.—Bullae reappeared on the hands and feet. Purpuric lesions were seen on the inner aspects of the right thigh and over the shins. Subconjunctival haemorrhages occurred. The general condition had clearly deteriorated, and there was evidence of much loss of weight.

February 20.—The patient was readmitted to hospital. The facial appearance was most remarkable: a livid purplish erythema involved the whole face except for the orbit. Ringed macules, not unlike the target lesions of erythema multiforme, were seen on the trunk. Many infiltrated bluish papules were scattered over the front of the chest and abdomen. These were almost certainly specific leukaemic infiltrations, but in view of the patient's general condition a biopsy was not carried out. All superficial lymph nodes were enlarged. The spleen extended to below the umbilicus. A blood count showed: haemoglobin, 60%; total leucocytes, 265,000 (lymphocytes 97%, polymorphs 3%). The bleeding-time was 5 minutes 45 seconds; the coagulation time 3 minutes 32 seconds. The platelet count was 60,000 per c.mm.

February 23.—Pharyngitis, with systemic upset, and copious vomiting were present. The mouth was painful, with multiple ulcers. A swab from the throat showed a few haemolytic streptococci.

March 12.—She now had a gastro-intestinal upset, with haematemesis and diarrhoea. Pathogenic organisms were not isolated from the faeces.

March 20.—Her general condition was deteriorating rapidly. The skin lesions, however, were fading noticeably. The bullae on the palms and soles had practically disappeared.

March 26.—The patient collapsed with abdominal pain and died a few hours later. This was thought to be probably due to a severe internal haemorrhage. A post-mortem examination was not made.

I wish to thank Dr. A. G. Smith for permission to report this case, and Drs. A. Christie and Morgan Hall for their co-operation in the pathological investigations.

Last year the New York State Legislature adopted an amendment excusing every pupil from "such study of health and hygiene as conflicts with the religion of his parents" (*New York Times*, January 6). This amendment, sponsored by the Christian Science Church, did not attract much attention until recently, when the New York Academy of Medicine and various teaching groups in the State demanded its repeal. They maintain that it would set back the cause of medicine and health; on the other hand the Christian Scientists state that the exemption of such children from health courses should not affect the examination questions which other children are required to answer. Their officials say that their only concern was that children of their faith whose parents request it should be permitted not to study disease symptomatology and the germ theory of disease causation. Every phase of "positive" health and hygiene is being studied by the children of Christian Scientists.

OVARIAN DENERVATION FOR OVARIAN DYSMENORRHOEA

A REVIEW OF 70 CASES

BY

The Late D. C. WISEMAN, F.R.C.S.Ed., M.R.C.O.G.

AND

W. M. THOMAS, D.Obst.R.C.O.G.

(From the Royal Infirmary, Preston)

Cotte (1925a, 1925b) first drew attention to the ovary as a source of pain in some cases of dysmenorrhoea. L'Hermitte and Dupont, in 1929, and O'Donel Browne (1939a, 1939b) suggested that a painful ovary could be rendered insensitive by denervation—an operation much less severe than presacral neurectomy. O'Donel Browne has shown a cure rate of 80.9% in his series of cases.

We here present 70 cases of ovarian dysmenorrhoea treated by bilateral ovarian denervation. Resection of the ovary was undertaken if the ovary was cystic, and Gilliam's suspension if the uterus was retroverted; appendicectomy was performed in most of the cases. Histological examination of the appendix was made in cases of right-sided pain. We do not consider these additional procedures to have influenced the results.

The ages of the patients were as follows:

Age	No.	Age	No.
Under 20	2 (2.8%)	30-34	11 (15.7%)
20-24	22 (31.4%)	35-39	8 (11.4%)
25-29	26 (37.2%)	40-45	1 (1.4%)

Thirteen of the patients were unmarried. Of the 57 who were married, 33 (58%) were nulliparous and 24 (42%) parous.

Nerve Supply of Ovary.—Sympathetic fibres from the tenth, eleventh, and twelfth dorsal and the first and second lumbar segments reach the ovary via the renal intermesenteric and coeliac plexuses by way of the infundibulo-pelvic ligaments. These are vasoconstrictor. Little is known of the parasympathetic supply except that its action is vasodilator. The sympathetic supply is bilateral. Sympathetic nerve fibres may reach the ovary also by way of the ovarian branch of the uterine artery—these emanating from the presacral trunk.

Diagnosis

Site of the Pain.—In 42 cases (60%) the pain was on the right side, in 22 (31%) on the left side, and in 6 (9%) it was bilateral. It was located in the iliac fossa.

Relation to Menses.—In 28 cases (40%) the pain was premenstrual, in 21 (30%) it was intramenstrual, and in 21 (30%) it was not related. Thus in 70% of the cases pain was related to the periods.

Type of Menstrual Loss.—Menorrhagia occurred in 16 cases (23%), oligomenorrhoea in 9 (13%), and the loss was normal in 45 (64%).

Type of Menstrual Cycle.—The cycle was regular in 61 cases (87%) and irregular in 9 (13%).

The deep sensibility reflex was first described by O'Donel Browne. Bimanual compression of the ovary accurately reproduces the pain of which the patient complains. Only where this test was positive did we consider the case to be one of true ovarian dysmenorrhoea.

Operative Procedure

A midline subumbilical paramedian incision was used. The infundibulo-pelvic ligaments were divided between clamps as near to the ovary as possible so that all the nerve fibres might be included in the clamps. The divided ends were ligated with catgut and care was taken when ligating the medial pedicle that the Fallopian tube was not kinked. If the ovary tended to fall into the pouch of Douglas the ovarian ligament was shortened by a catgut stitch.

The following additional procedures were carried out: Gilliam's suspension in 12 cases (17%), cyst resection in 34 (49%), appendicectomy in 19 (27%), and myomectomy in 3 (4%). All cases in which cyst resection was done had either follicular or corpus luteum cysts.

Results

The cases were examined six weeks after operation. In the follow-up carried out the interval of time elapsing after operation varied between three years and six months. Sixty-five out of 70 replied to the questionnaire.

Six weeks after operation 56 cases (80%) were cured, 12 (17%) were improved, and 2 (3%) were unchanged. At a follow-up of 65 cases undertaken over a period of from six months to three years, 32 (49%) were found to be cured, 29 (44.5%) were improved, and 4 (6.5%) were unchanged.

Comment

It is shown that bilateral ovarian denervation—a simple operative procedure and one not associated with a mortality or morbidity higher than those of laparotomy—cures or greatly diminishes the pain in ovarian dysmenorrhoea.

No case was considered to have any uterine dysmenorrhoea, and in every case the infundibulo-pelvic ligaments were completely divided; yet the pain was still present to some extent after a period of three years in 33 cases (51%) of those followed up. However, in only four cases (6.5%) was there no improvement.

We believe the explanation to be that the sympathetic supply in a percentage of women reaches the ovary along the ovarian branch of the uterine artery. The fibres are therefore a part of the presacral nerve. The following case history seems to confirm this explanation.

A 1-para aged 28 complained of severe right-sided intra-menstrual pain of four years' duration. Plication of the right ovary and appendicectomy had been carried out three years previously without relief. The menses were regular and the loss was normal. She was seen on August 24, 1948, and bimanual compression of the ovaries accurately reproduced the pain of which she complained. On April 22, 1949, bilateral ovarian denervation and Gilliam's suspension were carried out. She reported again 16 months later, as her symptoms were unchanged. Bimanual compression of the ovary again accurately reproduced the pain. As the ovaries were still acutely sensitive we considered that possibly the painful stimuli were reaching them via the presacral nerve along the ovarian branch of the uterine artery. Presacral sympathectomy was therefore performed on September 30, 1950. The pelvic organs at operation were normal. She reported on February 28, 1951—that is, five months after operation—having experienced no pain whatever with her periods. The ovaries were now insensitive on bimanual compression.

Right-sided Pain in Relation to Appendicitis.—Pain was right-sided in 42 cases and bore no definite relation to the menstrual cycle in 21. The condition may there-

fore sometimes be diagnosed as appendicitis. In all cases in which we performed appendicectomy, histological examination of the appendix showed no pathology. In 13 cases previous appendicectomy had produced no change in the symptoms. It therefore seems reasonable to suggest that when appendicectomy is carried out in a young woman, unless the appendix shows definite signs of acute inflammation, bilateral ovarian denervation should also be performed. This necessitates using a paramedian or Battle's incision, but does not add to the operative risk.

Resection of Cysts.—Retention cysts were removed routinely because of the difficulty in deciding which were physiological and which were pathological. Although resection of corpus luteum or follicular cysts was undertaken in 34 cases (48%) we do not consider this to have influenced the results, as every gynaecologist has seen many such cysts in insensitive ovaries.

Effect on Ovulation.—In 10 (14%) the menstrual loss was diminished after operation; in 20 (29%) it was increased, and in 40 (57%) unchanged. It will be noted that the tendency is for the loss to be increased as a result of the operation. Of the 57 married women 9 (16%) later became pregnant. We therefore assume that ovulation is not affected by division of the ovarian arteries.

Summary

Seventy cases of ovarian dysmenorrhoea treated by ovarian denervation are surveyed.

This operative treatment is undertaken only when bi-manual compression of the ovaries accurately reproduces the pain.

Ovarian denervation should be practised in young women in whom definite appendicitis is not found at operation.

Relief was obtained in 93.5% of cases.

Eighteen of the cases were under the care of Mr. R. M. Corbet, and we wish to thank him for permission to include them in this series.

Malaria has always been the greatest single medical problem for the Army in Malaya, but the War Office states that the disease rate is now under 2% in a year. New methods are being sought—for instance, "paludrine" has in the main supplanted mepacrine as a suppressive, and anti-mosquito measures are augmented by a steady flow of ingenious devices. There has been some speculation about paludrine-resistant strains, although there is no evidence as yet. Nevertheless, there was a recrudescence of malaria last summer. Dysentery and diarrhoea are present throughout the year, with a monthly incidence of between two and three cases per 1,000 troops, the early summer providing the higher figures. Skin complaints are at about three times the rate encountered in England. This may be due to jungle conditions, though in some respects the jungle shields the soldier from infective hazards met with in cantonments. What is more certainly a result of deployment in the jungle is scrub typhus, a few cases of which still occur regularly in spite of the use of clothing impregnated with a mite-killer (or more probably because of a lapse in its use). Finally, as might be expected in a country stretching almost to the equator, cases do occur of heat exhaustion, but there are not many of them. Other than the diseases mentioned and venereal disease, the sickness experience in Malaya is perhaps 15% higher than at home.

EPIDEMIOLOGY OF A HUMAN CASE OF BACILLARY DYSENTERY DUE TO INFECTION BY SHIGELLA FLEXNERI 103 Z

BY

K. PATRICIA CARPENTER, M.B., Ch.B.
Dip.Bact.

Dysentery Reference Laboratory, Oxford

AND

B. R. SANDIFORD, M.D.

Public Health Laboratory, Birmingham

It is often extremely difficult to trace the source of infection of a sporadic case of bacillary dysentery, and since phage-typing, which has proved so valuable in the epidemiology of salmonella and staphylococcal infections, is not in general use for shigella infections, knowledge of the precise biochemical and serological type of the strain concerned may provide the only guide to the possible source of infection. The point is well illustrated in the following case, in which the source of infection was traced beyond reasonable doubt to contact with an infected monkey.

On February 8, 1951, a specimen of faeces from a girl of 2 years 5 months stated to have dysentery was sent for bacteriological examination to a public health laboratory, and from it an organism giving the biochemical reactions of *Shigella flexneri* was isolated. It was agglutinated by the Standards Laboratory's *Sh. flexneri* Z and *Sh. flexneri* 103 sera, and was subsequently confirmed by the Dysentery Reference Laboratory as a typical *Sh. flexneri* 103 Z, as described in this country by Rewell and Bridges (1948). Though this organism has only once been reported from a human case of dysentery in this country (and the infection may in that case have been acquired in the Middle East), it is a frequent cause of bacillary dysentery in primates imported into Great Britain. In view of this, further investigation into the history of the case was undertaken to try to establish any possible contact with monkeys, and an interesting story was unfolded.

On February 1, 1951, the child was taken by her mother to the Pets' Corner of a large general store where there were several cages of monkeys. While watching them the child was eating an ice-cream cornet, and one of the monkeys put its paw through the cage to grab the cornet. Though the child held on to it, the ice-cream was touched by the animal, and she licked the cornet before the mother could throw it away.

Two days later the child appeared off colour, refused her lunch, and by evening had frequent motions. By February 5 the faeces contained blood and mucus, and medical advice was sought on February 7, when the child was having five or six motions a day, which was stated to be less than when she originally became ill. Apart from diarrhoea, the child had few constitutional symptoms, and difficulty was experienced in keeping her in bed. She was treated with a six-day course of succinyl-sulphathiazole, and, though two faecal specimens received on February 21 and 23 yielded no pathogenic organisms, *Sh. flexneri* 103 Z was again isolated from a specimen received on March 1. A further six-day course of succinyl-sulphathiazole was then given, and the organism was not found in subsequent specimens.

When questioned, the mother admitted to some diarrhoea herself during the child's illness, but she was

symptomless when two samples were taken, and the organism was not isolated from either.

After the positive history of contact with monkeys had been obtained the Pets' Corner was investigated with the full co-operation of the store management. The Corner was clean and well looked after, and no faeces were seen in the cages. The monkeys had all been in the store for nearly two years without any recent imports. Both the manager and the visiting veterinary surgeon stated that the animals had been healthy and had had no diarrhoea during this time.

The monkeys were arranged in the room in three main groups. In the centre of the room was a cage containing 13 monkeys, some being the common rhesus monkey, *Macaca mulatta*, and others the West African green guenon, *Cercopithecus sabaeus*. This was apparently the most popular cage. On one side was a small cage containing a mother and baby of the rhesus type, and on the other side was a row of three cages containing the same type and also the mona guenon, *Cercopithecus mona*. This row of cages was separated from the public by a breast-high iron bar with wire netting between the bar and the floor. Because of the bar, the manager thought it very unlikely that the monkey concerned could be in these cages, and, as the mother was vague regarding which cage they had been watching when the incident happened, attention was concentrated at first on the centre cage and the small side cage.

By chasing the monkeys round to startle them a number of freshly passed faeces were obtained, but no intestinal pathogens were isolated from these. It was arranged that specimens of faeces found in each cage in the morning would be sent to the laboratory. Between February 21 and March 15, 69 such specimens were examined, but no shigellae were isolated, though one sample from the centre cage yielded *Salmonella typhimurium*. All the faeces examined were formed and none contained blood or mucus. It was then decided to take rectal swabs, and on February 16 the mother and baby rhesus monkeys and the occupants of the centre cage were swabbed, but no pathogens were subsequently isolated. However, a sample taken from a cage floor on March 15, the day it was decided to abandon this method, yielded an organism confirmed as *Sh. flexneri* 103 Z. This specimen was found with surprise to have come from the middle cage of the side row of three. Unfortunately, between the time of sampling and the isolation of the organism the five monkeys in this cage had been sent to different parts of the country, so that rectal swabs could not be obtained from them.

A further interview with the mother then elicited the fact that she was probably holding the child in her arms at the time of the incident, and subsequent examination of the protective barrier showed that, if this were so and the child had been held forward over the bar, the monkey could have touched the ice-cream cornet.

Discussion

In spite of the fact that it was too late to trace the actual monkey concerned, there seems little doubt that the child was infected by eating the ice-cream freshly contaminated by the monkey's paw; and the habits of monkeys doubtless indicate the source of contamination of the paw. As there was no time for multiplication of the organism in the ice-cream the infecting dose was presumably confined to that directly transferred from the animal's paw.

Though it has been recognized for many years that primates are naturally susceptible to infection by certain organisms of the *Shigella* genus, seldom have such animals been shown to be directly responsible for human infection. Rewell (1949) reported possible infection of a monkey-house keeper in this country with *Sh. schmitzii* from a lar gibbon, and refers to a family outbreak of bacillary dysentery in Hamburg, probably arising from pet monkeys, reported by Bach, Fulscher, and Harnack (1931). Rewell and Bridges (1949) have drawn attention to the potential danger to personnel handling monkeys during their rapid air transport to this country from abroad.

It is apparent from experience at the Dysentery Reference Laboratory and from personal communications from those in charge of monkey-houses in this country that primates can be infected with almost every type of *Shigella*; but undoubtedly the most common infecting types are *Sh. flexneri* 103 and *Sh. flexneri* 103 Z. The clinical picture of the animals varies from a rapidly fatal dysentery to a symptomless carrier state. On the other hand, infection due to *Sh. flexneri* 103 Z is rare in man. In all probability, if the child had been infected with one of the more common human *Shigella* types, such as *Sh. sonnei* or *Sh. flexneri* Z, the story of the monkey's paw might never have been obtained.

It is surprising to find that, although at least two of the monkeys in the Pets' Corner were at one time or another excreting such pathogens as *Salm. typhimurium* and *Sh. flexneri* 103 Z, both highly infective to the species, no outbreak occurred amongst the animals. Possibly the fact that it was an established colony with no recent imports may have been responsible.

Admittedly, monkeys in this country are generally in relatively closed communities, but many such colonies are open to the public, and the measures to prevent contact between the monkeys and their visitors may not always be completely adequate to protect the one from the other. As a large proportion of such visitors are children, who are highly susceptible to both shigella and salmonella infections and who frequently on such occasions are eating titbits equally enjoyed by monkeys, a real danger would seem to exist. This could be prevented by the provision of foolproof barriers.

Summary

A case of bacillary dysentery in a child due to the rare human pathogen *Sh. flexneri* 103 Z is described, and an account is given of the investigations to trace the source of infection to monkeys, which was indicated by the fact that the organism is a common cause of dysentery in these animals. In addition to the isolation of *Sh. flexneri* 103 Z from monkey faeces in one cage of the Pets' Corner concerned, *Salm. typhimurium* was obtained from a specimen taken from another cage.

Warning is given of the potential danger, in animal-houses open to the public, of the transmission of shigella infection from monkeys to their visitors.

Our thanks are due to Mr. B. Spencer, F.I.M.L.T., for his technical assistance; the manager of the Pets' Corner for his willing co-operation; to Mr. E. Copeland, M.R.C.V.S., for his assistance in obtaining specimens from the monkeys; and to Dr. Gedy for the specimens and clinical data from the patient.

Medical Memorandum

Congenital Indifference to Pain

Congenital indifference to pain is a rare condition. A survey of the English and American literature since 1900 has revealed only 10 previous cases (Dearborn, 1932; Ford and Wilkins, 3 cases, 1938; Kunkle and Chapman, 1943; Arbuse, Cantor, and Barenberg, 1949; Boyd and Nie, 1949; Duncan Leys, 1950; McMurray, 1950; Farquhar and Sutton, 1951), with brief references to eight others (Critchley, 2 cases, 1934; Grain, 1949; Nielsen, 2 cases, 1949; Keizer, 3 cases, 1951).

Case Report

A girl aged 6 was admitted to Poole General Hospital in November, 1949, with a provisional diagnosis of "rheumatoid arthritis." In May, 1949, she had had a febrile illness with cough and haemoptysis which rapidly responded to a course of sulphonamide. Two weeks after recovery the right knee had become swollen, gradually subsiding over a period of three weeks. In July the left ankle became swollen and remained so; shortly before admission the right ankle had also swollen a little. Despite a limp, she remained lively and active and had never complained of pain in the affected joints. The past medical history was otherwise not relevant.

She was a shy, carrot-haired girl of normal height and weight for her age and of average intelligence. The teeth were very carious. There were extensive areas of scarring, superficial ulceration, and keloid formation on the outer side of the thighs and multiple scars on both knees. The cardiovascular system was normal; blood pressure 105/50. Her chest was clear and the liver and spleen were not palpable. There was a brawny, diffuse, non-tender swelling of the left heel and instep and a similar smaller swelling of the right ankle. There was no limitation of movement at any joint. Fundi and pupils were normal. All deep reflexes were present and equal, with flexor plantars. It was noted that she watched attempted venepuncture with amused interest, and further examination revealed that she was completely indifferent to pain over the entire body surface: pinching, pricking with pins, and firm pressure on the tendo Achilles were all tolerated without flinching or apparent discomfort. She was, however, able to distinguish between "sharp" and "blunt" without error. There was normal appreciation of light touch, heat, cold, vibration, and joint sense. There was no dysphasia, agnosia, apraxia, or astereognosis. She was right-handed.

A radiograph of the feet showed fragmentation and displacement of the epiphysis of the left calcaneum, erosion and fragmentation of the right talus, and erosion of the proximal articular facet of the right cuboid. There was a right-sided coxa vara and a congenital unfused neural arch of T12 vertebra. Biopsy of the left calcaneum showed no abnormality. A Mantoux test to 1:100 and blood Wassermann reaction were negative. Bone structure was normal radiologically apart from prominent Harris's lines at the lower end of the fibula, tibia, and femur.

Further inquiries elicited that she had never at any time complained of or appeared to feel pain: she had often fallen flat on her face on concrete and got up laughing; while playing with other children handfuls of hair had been pulled out without her showing any concern. She had never complained of toothache, headache, or abdominal pain. Since infancy she had been a hyperactive restless child, spending her time running, climbing trees, and jumping off walls. The bony lesions of the feet were considered to be a sequel to multiple minor injuries, and with a period of strict rest in bed partial recalcification occurred. In July, 1950, she was again referred to hospital complaining of inability to "jump over a tennis net as well as usual." She

was found to have a subtrochanteric fracture of the right femur with marked callus formation. The actual circumstances of the fracture could not be elicited, but again there was no complaint of pain.

Comment

In 1932 Dearborn recorded, under the title of "A Case of Congenital Pure Analgesia," the history of a man of 54 who had never experienced any pain throughout his life. He had sustained, among other injuries, a blow in the face with a pickaxe, a bullet through a finger, a broken nose, severe laceration of the knee, and a burned hand—all without apparent pain. In later life he appeared in American vaudeville as "Edward H. Gibson, the Human Pincushion," allowing the audience to stick up to 50-60 pins into his body at a time, and on one occasion to hammer a nail through his hand. Subsequent reports have all emphasized the frequency with which multiple painless fractures, dislocations, lacerations, burns, and their sequelae in the form of scarring, deformities, keloid formation, and painless osteomyelitis occur in these subjects.

Acquired indifference to pain has been described in lesions of the posterior parietal area of the dominant hemisphere, especially those involving the supramarginal and angular gyri, and is usually associated with other gross neurological defects. The possibility that congenital indifference to pain is due to a similar structural lesion of the parietal cortex must, however, remain speculative in the absence of necropsy material. Ford and Wilkins suggested that the condition was due to a "congenital dysplasia involving the neural mechanisms concerned in the perception of pain"—similar in nature to congenital word-deafness, word-blindness, and colour-blindness, in which structural lesions are known to be absent. The presence of a mild congenital word-blindness in one of their cases supports this contention.

I wish to thank Dr. J. R. Hindmarsh for permission to publish this case; and Dr. F. Parkes Weber for his advice.

La Presse Médicale (January 12) reports that an international foundation has been created to commemorate the work of the bacteriologist Charles Nicolle (1866-1936). Among his studies were investigations on the spread of typhus by insects, on subclinical infection and carriers, and on the prophylaxis of measles by convalescent serum. The foundation has its headquarters in Paris, and it has been decided to erect a fountain in Tunis, where much of Nicolle's medico-social work was accomplished, and to establish—probably also in Tunis—a clinic and laboratories specializing in the fight against infectious diseases and those due to parasites, but especially syphilis and trachoma.

TOO MANY PEOPLE

Human Fertility: The Modern Dilemma. By Robert C. Cook. With an introduction by Julian Huxley. (Pp. 351. £1 1s.) London: Victor Gollancz. 1951.

This book should be of particular interest to members of the medical profession, since the author discusses two problems in the creation and development of which medicine has played an outstanding part. Medical intervention in the affairs of a human population is followed by a fall in the death rate, by an uprising in the survival rate, and by a magnification of the natural increase. Indeed, it is by this fall, this uprising, and this magnification that the quality of the service that medicine renders to a population is partly assessed.

In the history of a population in which the kind of medicine that we know has found a place, a growing disharmony between the total population numbers and the total resources of the habitat develops. This disharmony is expressed in various ways, such as poverty, insecurity, and the mounting threat of starvation. Attempts to check or to reverse this process usually take the form of the eager encouragement of increased food production and of a planned industrialization of the society. But for these a great deal of time is required, and it therefore becomes necessary for the population to control its fertility and for the State to facilitate the provision of the means for so doing. The remote repercussion of medical intervention undertaken without due regard for its effects is the creation of the need for a planned population policy.

The author argues, and supports his argument by particular reference to Puerto Rico, that unbalanced and unchecked fertility is ravaging many lands like a hurricane. Nearly four-fifths of the people of the world to-day subsist near the verge of starvation. No matter what may be done to increase food production, the rate of the increase cannot equal the rate at which the human population of the world itself is multiplying. The only possible method of checking this growing disharmony is by the production of a simple, foolproof contraceptive tablet, no more expensive than an aspirin, that will produce temporary sterility when taken by the mouth. This, in the author's opinion, would offer mankind a good deal more promise of security than any world-wide agreement to outlaw war.

The author then discusses the even more debatable and complex problem of population quality. He states the argument that the innate quality of the human stock of a country such as Britain tends to degenerate progressively generation by generation. With admirable fairness he reproduces the argument that the relaxation of natural selection brought about by the intervention of the medical and social sciences in the affairs of a population must be causing slow degeneration of the stock through the accumulation of harmful mutations. He then puts forward proposals whose object is to encourage reproduction by the more intelligent and the more highly endowed. It is most desirable that members of the medical profession shall be well informed about both these matters and shall have reached, through examining the available evidence, a conclusion on their importance and on the ways in which the problems shall be tackled and solved.

F. A. E. CREW.

THE NUTRITIONAL REVOLUTION

The Nutritional Improvement of Life. By Henry C. Sherman. (Pp. 270. £1 4s.) New York: Columbia University Press. 1950. London: Geoffrey Cumberlege. 1950.

Nutrition Work in Greece. By Andr  mache G. Tsongas. (Pp. 67. U.S. \$0.50.) Rome: Food and Agriculture Organization of the United Nations. 1951.

Teaching Better Nutrition. By Jean R. S. Ritchie. (Pp. 148; illustrated. \$1.50.) Washington: Food and Agriculture Organization of the United Nations. 1951.

H. C. Sherman has spent the best years of his life in nutritional research and teaching, and in his latest book he tells the story of the development of our knowledge and its possibilities for the betterment of mankind. In the first chapter he discusses the gradual appreciation in Britain and the U.S.A. of the importance of sound nutrition for the welfare of every man, woman, and child. He then goes back to the beginnings of nutrition as a science, and describes the pioneer work of Atwater in the 'nineties on food tables and calorie requirements. There follow chapters on the progress made in each of the first four decades of the present century; energy requirements, Chittenden's protein minimum, the importance of mineral elements, and the dawn of the vitamin era are all discussed. In the chapter covering the first world war he describes the development of the idea that proteins might differ in their nutritional value according to their constituent amino-acids, and discusses the discovery and investigation of the three primary vitamins A, B, and C, but says little about the impact of the first world war on national food supplies and all that this involved. Multiplication of the vitamins and the extensive study of their biological functions in the 1920's led to the concept of optimum nutrition; the author traces the expansion of this idea throughout the 1930's. The scientific classification of rickets as a deficiency disease and its eradication from the big cities receives surprisingly little attention, however, and Sir Edward Mellanby's name does not appear at all in a bibliography which must include about 400 references.

The importance of ensuring good national nutrition was appreciated during the opening phases of the second world war, and the handling of the situation in Canada, the U.S.A., and Britain is briefly described. The latter part of the book is on rather more theoretical subjects. The nutritional aspects of the internal environment, for instance, and the relationship of nutrition to the expectation and length of life are discussed, and the implications of all this growing body of knowledge, not only for national nutrition but in the general service of man. The book closes with an appreciation of the National Research Council's recommended dietary allowances.

Nutrition Work in Greece describes the work carried out in that country by F.A.O. after the period of emergency tided over by the Unrra organization had come to an end, and shows, as it were, the practical outcome of the developments outlined by Sherman.

The author of *Teaching Better Nutrition* describes how the newer knowledge of nutrition can be got across to backward peoples, where it can do so much good. It is a pity that Hopkins's experiments in 1912 should have been given the misleading and erroneous caption, "Hopkins' discovery of vitamin A," but in general the information given seems to be correct.

These books form an interesting set of three, but to most people they will not have an equal appeal.

Sherman's is a book for the student, the F.A.O. publications for teachers and workers in the field. The triumphs they describe are impressive, but were they so difficult to win? The hard task lies ahead. Country after country is outgrowing the food it can produce, and behind the successes of the scientists stands the spectre of world famine. Technical experts in nutrition may shrug their shoulders and turn away to their pleasant jobs with the feeling that it is not their business. They may be right; in the narrow sense they are right. But let us hope that future historians will not look back upon the nutritional revolution and condemn those who brought it about as little men who failed to grapple, while there was still time, with the greatest crisis in world history.

R. A. McCANCE.

FOR STUDENTS OF ORTHOPAEDICS

Regional Orthopaedic Surgery. By Paul C. Colonna, M.D. (Pp. 706; 474 figures. £2 17s. 6d.) Philadelphia and London: W. B. Saunders Company. 1950.

The author is to be congratulated on producing a book which should prove of real value to orthopaedic students, both undergraduate and postgraduate. After two introductory chapters on the physiology and general pathology of bones and joints the remainder of the work is arranged regionally. For the purpose of teaching this arrangement has much to recommend it. Each chapter opens with a short section on applied anatomy followed by a description of the soft-tissue injuries, fractures, tuberculous lesions, and orthopaedic conditions of the region concerned.

By concentrating on the features which are of importance to students the author has been able to cover the whole field of orthopaedics and fractures. The illustrations, which consist of line drawings, photographs, and reproductions of radiographs, are excellent. Some of the recommendations on treatment have an American flavour which may not be entirely acceptable to students in Britain. The book concludes with two excellent chapters on orthopaedic apparatus and physiotherapy. There are few orthopaedic textbooks which satisfy the needs of the student in such a masterly manner.

J. S. BATCHELOR.

FICTION AS FACT

My Dear Holmes. A Study in Sherlock. By Gavin Brend. (Pp. 183. 10s. 6d.) London: George Allen and Unwin. 1951.

It may be a dangerous procedure to create a character in fiction. If Conan Doyle could have anticipated the great popularity which his detective hero would evoke from the English-speaking public, he might have hesitated before creating him. As it was, he appeared to get tired of his hero and killed him off, to the bitter disappointment of his public. Popular demand and perhaps economic reasons induced him to bring Sherlock Holmes into action again. It was inevitable, however, that many inconsistencies of fact would appear in a series of disconnected tales written at the publisher's urgent request.

In this attractive little book the author has attempted to reconcile many of the inconsistencies, a task which assumes that there was a factual basis behind the fiction. Those who almost believe that Sherlock Holmes was a real person will be delighted to learn the year of his birth and the approximate dates of most of his adventures; they will be interested to probe the secrets of

Watson's two marriages and of his quarrel and reconciliation with Holmes. This is indeed a book which all Sherlock Holmes's fans will be eager to read. It is also a book for the philosopher to study, for here he will behold fiction treated as fact, and a myth in process of becoming a belief.

ZACHARY COPE.

BOOKS RECEIVED

Review is not precluded by notice here of books recently received

A Textbook of General Physiology. By H. Davson, D.Sc. (Pp. 659. 45s.) London: J. and A. Churchill. 1951.

Anaesthetics for Medical Students. By G. Ostlere, M.A., M.B., B.Chir., D.A. 2nd ed. (Pp. 108. 8s. 6d.) London: J. and A. Churchill. 1951.

Massage and Medical Gymnastics. Revised by E. M. Tod, M.C.S.P., T.M.M.G. 4th ed. (Pp. 224. 16s.) London: J. and A. Churchill. 1951.

SATURDAY JANUARY 19 1952

THE EFFICACY OF B.C.G. VACCINATION

Research done as an afterthought has its pitfalls. Data which were not originally collected for a specific investigation may need to be analysed in retrospect. If, say, patients were treated with drug A in one hospital in 1946, and in 1948 the records of another hospital show that patients with the same disease were treated with drug B, can a fair comparison of the results be made? Useful information may be gained, but such investigations are full of traps for the unwary. A recent report¹ on "The Efficacy of B.C.G. Vaccination" is a retrospective comparison of this kind on a big scale. The authors, Dahlström and Difs, have studied the incidence of tuberculosis in conscripts who entered the Swedish Army between 1941 and 1944. Most conscripts were tuberculin tested. B.C.G. inoculation was offered to the 61,474 who were negative, and 36,235 (59%) accepted. Dahlström and Difs turned back to the records to study the morbidity from tuberculosis during Army service of the inoculated and of the 25,239 men who refused inoculation. This was possible because every case of tuberculosis or suspected tuberculosis in the Swedish Army is reported to the National Insurance Office. To ensure uniform assessment of the radiological findings the authors borrowed and reviewed the x-ray films of the reported cases (but they do not say in how many cases they were not able to see the films).

For the analysis of morbidity they have tried to distinguish those early tuberculous manifestations which could have resulted from a primary infection contracted shortly before or shortly after the date of vaccination (which developed, that is, before any protection conferred by B.C.G. could begin to operate). Under this heading come cases of primary tuberculosis arising within two months of inoculation, and pleurisy and other post-primary signs of disease arising within six months. Aware of one main weakness of the trial—namely, that the control group were those who refused inoculation and may therefore have been different in character—the authors offer evidence that the inoculated and control groups were in fact comparable at the start by recording the "early"

morbidity for the two groups. During the first 60 days the incidence of primary tuberculosis in the vaccinated soldiers was 0.75 per 1,000; in the non-vaccinated it was 1.35 per 1,000. The difference being "not statistically significant," Dahlström and Difs conclude that the risk of acquiring primary tuberculosis was equal in the two groups prior to the onset of any protection that B.C.G. might afford. A similar analysis is applied to cases of post-primary tuberculosis: during the first six months the incidence was 1.52 per 1,000 in the vaccinated group, and 1.47 in the controls. It must be noted that the conclusion on equality of risk might apply to equal risk of infection in the first weeks of service, or to equal susceptibility, or to both combined: the analysis does not, nor could it, distinguish between the two. However, an investigation of the incidence of non-specific pneumonia in the follow-up period showed similar figures for the two groups.

Having found that the groups were comparable at the beginning of the study, the authors then analysed the subsequent morbidity—that is, all the cases other than the early ones. The difference between the two groups is impressive. After the first two months signs of primary tuberculosis were seen in 31 of the vaccinated (0.86 per 1,000) and 106 of the controls (4.20 per 1,000). After the first six months 46 cases of pleural effusion were noted in the vaccinated (1.27 per 1,000) and 145 in the control group (5.75 per 1,000). Post-primary pulmonary tuberculosis was seen in 15 of the vaccinated (0.41 per 1,000) and 37 of the controls (1.46 per 1,000). These differences are statistically significant, and the evidence in favour of B.C.G. appears to be very strong.

But the authors, while trying to be objective in retrospect, are not entirely so. Early in their analysis they write: "Generally speaking, the diagnosis was somewhat easier to establish in the (originally) tuberculin-negative than in the vaccinated group, being helped by the conversion from the non-reactive to the reactive state." Does this mean that a lesion in a person becoming tuberculin-positive without the aid of B.C.G. was presumed tuberculous unless the contrary was proved, but in a vaccinated person was presumed non-tuberculous unless definite proof was forthcoming? Doubtful cases amounted to 16 in the vaccinated group and seven in the controls, and the authors remark that "the smaller number in the latter group is understandable because the tuberculin reaction provided better help in making the diagnosis." This surely means that, in the control group a number of cases which would have been considered doubtful had they been vaccinated were considered certain. How many there were in this

¹ *Acta tuberc. scand.*, 1951, 25, Suppl. 27.

category is not known, but the question seriously affects the data on primary morbidity. If the authors' own objectivity were alone in question there might be little cause for concern. But the diagnosis was not dependent on them alone; they could consult only the records of cases notified as tuberculous or suspected to have tuberculosis. If a case was considered non-tuberculous by the medical officer of the unit, then presumably it did not appear in the insurance records which the authors consulted. It is conceivable that in doubtful cases a medical officer might reject a diagnosis of tuberculosis when he knew that the man concerned had received B.C.G.: such enthusiasm is not unheard of.

The authors' use of statistical analysis also tends to be misleading. When, in analysing early morbidity, they find that a difference between the two groups (as in the figures already quoted of 0.75 per 1,000 in one group and 1.35 in the other) is not statistically significant, they conclude that the two groups are *therefore* comparable or similar. This type of reasoning occurs at several points and is quite unjustifiable. If one death occurs among four patients treated with drug X and three deaths in four patients treated with drug Y, the difference is not statistically significant because the totals are small, but this does not warrant the conclusion that the effect of the two drugs is the same. The fact that other figures in the analysis provide more valid evidence of equal risk at the start does not justify the false logic in the first place.

The main defect of the analysis, however, is that, while the authors offer evidence that the two groups were comparable at the beginning of their Army service, they are not able to show that conditions were comparable during the service—that is, during the time when the men were developing signs of disease. The reader might assume at first that the proportions of inoculated men and controls were about the same in each Army unit, but on page 22 the authors write: "The incidence of vaccination probably depended more on the initiative and propaganda of the Army surgeon than on the initiative of the individual." This is understandable, and later there is evidence that in some units acceptance of B.C.G. was probably very high and in others low. In chapter 10 of their monograph the authors list "agglomerations" of tuberculosis in Army units in which at least five cases occurred among the men conscripted in the relevant year. Each of the agglomerations was in a different unit. In 16 units cases occurred only in controls; in one there were cases in both control and vaccinated groups, and in six units all the cases occurred in vaccinated men.

The total of vaccinated and unvaccinated men in each unit is not given. There were three "epidemics" which occurred in vaccinated men before protection had developed, with a total of 36 cases: in the units where these occurred there were no cases among the unvaccinated men, and the assumption is that all, or nearly all, men in these units were vaccinated. Three agglomerations of cases occurred in vaccinated men alone after the date of expected development of protection. Here two explanations are possible: either nearly all men in these units were vaccinated or the vaccinated were more susceptible to tuberculosis than the controls. If the latter explanation is rejected the reader is led to form a picture, presented by the authors' own statistics, of vaccinated and unvaccinated units rather than of vaccinated and unvaccinated individuals—a different kettle of fish entirely.

With this picture of a contrast between units rather than between individuals within the units, it would be reasonable to imagine that the same medical officers who persuaded their men to accept the vaccine might also make better arrangements for medical supervision, including routine x-ray examinations, and, on the other hand, that in units with unenthusiastic medical officers, or inefficient medical control, few men might be vaccinated and cases of tuberculosis remain for a long time undiagnosed, with consequent infection of other men in the same units. All this is not to say that such was the case; the point is that it may have been. The authors stress that in both groups the rate of incidence of primary infections fell after the first months, and conclude, no doubt rightly, that the fall was due to effective elimination of sources of infection at the beginning. But the fall was much less in the controls than in the vaccinated, and this might be due to less effective measures in the control units. The authors state that "there is not the slightest evidence . . . that the marked fall of the risk in the B.C.G. group could have been due to more effective weeding out of sources of infection in that group," but they offer no valid support for this statement.

That these objections have to be raised is a pity, for this Swedish study is a praiseworthy attempt to extract information from past records, a complex task at the best of times. In spite of the difficulties the analysis has produced much information of great interest, and there is no doubt that the evidence, with all its defects, is strongly suggestive. Similar studies in the past have been preoccupied with the manifestations of primary disease; here post-primary morbidity has been analysed in detail, and on this the authors are especially to be congratulated. They announce their intention of analysing later results in

the two groups, and we can hope that they may then be able to consider some of the points missed in their first report. In England there is now under way a large-scale controlled trial of B.C.G. and vole vaccines under the Medical Research Council: the groups are randomly selected, and this will avoid certain errors of the Swedish investigation. It is to be hoped that those in charge of the investigation will also be well aware of the many other errors that may creep in. No investigation dealing with human beings can be perfect, but, if the success of recent well-organized clinical trials of new drugs and vaccines can be taken as a guide, it should now be possible to reach on B.C.G. a verdict much more decisive than the "strongly suggestive" which applies to this excellent report.

THE BOTTLE OF MEDICINE

In the *Supplement* this week (p. 18) we publish a summary of a memorandum prepared for the Birmingham Executive Council on conditions of general practice. The authors of this document, after drawing attention to the cost of providing free medicine for the population, suggest that "the best cure for the bottle-of-medicine habit would be a different psychological approach, such as health education and the practice of preventive medicine." Many doctors are, of course, ready to educate their patients if given half a chance, and we recently reported a meeting¹ of the General Practice Section of the Royal Society of Medicine, at which Dr. R. J. F. H. Pinsent gave an account of a year's practice, during which he had classified all the forms of treatment that he had given. At approximately half his consultations during the year he had prescribed either specific or symptomatic treatment. In 40% of cases he had given treatment by health education, by argument, and by explanation of the patient's symptoms, and in the remaining 10% he had given a placebo. Many of the doctors who spoke in a subsequent discussion, while praising Dr. Pinsent's strength of mind in refusing to prescribe a bottle of medicine so often, were for their part not inclined to do the same for a number of reasons, of which the most important appeared to be that many of their patients who expected to receive a bottle of medicine would not come at all if this were denied them. If it is true, as one was led at this meeting to believe, that over general practice as a whole health education is given to about 10% of patients and a bottle of medicine as a placebo to about 40%—that is, the reverse of Dr. Pinsent's practice—it is possible to make a rough estimate of the cost of placebos.

In 1949 188 million prescriptions were dispensed in England. If 40% of these prescriptions were for a placebo, and if mist. alb. (the cost of 4 oz. of which is 1s. 7d., including the bottle and dispensing charge) is taken as typical, the annual cost of dispensing placebos would amount to £5½ million. To a certain extent the unreasonable demands of patients who expect attention for trivial complaints may be encouraged by lack of proportion in treatment, but against the cost of unnecessary bottles of medicine has to be put the cost of the time which doctors would have to spend in bringing their patients round to a more sensible attitude towards treatment.

Although a strong case can now be made on economic grounds for limiting the bottles of medicine prescribed in both hospitals and general practice, there is no question about the usefulness of placebos in therapeutics, nor about the fact that they have in some cases a more powerful effect than known pharmaceutical agents. Wolf,² for instance, studying the effect of placebos on the responses of the stomach, was able to show that the circumstances in which a drug was given could alter and even reverse the expected response. For example, he was able to alleviate nausea and restore normal gastric tone with a dose of ipecacuanha in a patient suffering from sickness of pregnancy by convincing her beforehand that such would be the effect of the medicine. Another interesting example of the psychological effect of a remedy was quoted by Best and his colleagues,³ who treated 42 patients with a complicated and alarming machine for irradiating the pituitary gland. With 18 of these patients the current was never switched on, and it was this group, receiving the same psychological treatment but no irradiation, which showed, if anything, the greater symptomatic improvement.

Individual cases in which a placebo has brought about a dramatic cure are familiar to all medical men: such cases, in fact, have formed the stock-in-trade of quacks for centuries. But are doctors justified in adopting similar methods and purposely deceiving their patients, however successful the results may be? A placebo can have the effect on a patient either of removing real symptoms and persuading him back to health or of persuading him that his imagined symptoms are caused by a real illness that can be treated with medicine. If this type of patient is treated with a bottle of medicine his symptoms, which are usually caused by anxiety and introspection, may become established and his demand for more medicine ensured.

Although the alternatives to treating a patient with a placebo cannot usefully be discussed without

¹ *British Medical Journal*, 1951, 2, 1335.

² *J. clin. Invest.*, 1950, 28, 100.

³ *Amer. J. med. Sci.*, 1950, 219, 276.

reference to the mentality and circumstances of the individual, there are some general rules to be observed. The intelligence of the patient is not a satisfactory guide, for reason loses its power when we think of our own health and the possibility of dying in the immediate future. In such circumstances a highly critical person may become quite gullible and, if he is enough afraid of illness and death, will trust anyone whom he believes to have the power to keep him alive. In considering the pros and cons of prescribing a placebo it is as well to bear in mind that, in spite of the great trust and esteem in which the medical profession is generally held, there is much mistrust in the minds of many people about the efficacy of its medication. Many patients are too polite to protest in the surgery, but consign the contents of their bottle to the kitchen sink, and it is certain that many packets of the iron tablets so liberally dispensed at antenatal clinics are stored out of sight in cupboards, and sometimes left in places where they may be a danger to children. Placebos should not be used for treating neurotic patients whose complaints are based on anxiety and fear of disease or for retaining the confidence of those expecting but not requiring treatment, but there are many real symptoms and diseases for which no specific treatment is offered by the *Pharmacopoeia*, and in these a placebo is often justified and can work wonders. The persuasion will be all the greater if the mixture contains a substance that will produce a subjective effect which the patient will notice. Such are the virtues of aspirin for deadening pain, of alcohol for producing internal warmth and well-being, and of turpentine for reddening the skin that it is easy to persuade patients of their efficacy in other ways undreamed of by pharmacologists. But it is a fallacy to suppose that an inactive medicine can do no harm. If prescribed in a perfunctory way for a patient needing explanation and reassurance it may increase faith in his disease rather than in the remedy, and a doctor who gives placebos in the wrong spirit may harm the patient.

THE SELECTION OF BUS DRIVERS

A good deal of evidence has accumulated in recent years to show that careful selection of bus drivers results in a reduction of the accident rate. Thus, for example, the application of selection techniques to Paris omnibus drivers is said to have reduced the number of accidents by 66% between 1929 and 1933. The Yellow Cab Company, Chicago, tested their drivers and found those classed as "unsatisfactory" on the selection tests had twice as many accidents as the "satisfactory" group.¹ In this country an inquiry was conducted by Farmer and Chambers,² who examined the accident records of

several groups of drivers and found that accident-proneness was an important factor. They gave psychological tests to the men and found that those who failed in the tests had a higher average accident rate than those who passed; the difference, however, was not great. Bus drivers have a high reputation for safety and courtesy—the connexion between these two qualities was recognized in a recent series of posters. How are they selected?

Generally speaking, many men have the "driving" personality, and there is no serious shortage of applicants, which makes possible a reasonable degree of selection. After a careful interview by specially trained and experienced staff who review the applicant's driving history, he is given a driving test on the road. He is then required by law to undergo a medical examination before he may obtain a licence to drive public service vehicles. It is here that the examining practitioner is required to exercise not only his private conscience towards his patient but also his public conscience towards the community. Men with defective eyesight or hearing, physical deformities likely to affect driving, and those with any condition likely to cause sudden collapse—to make a list of these is a good "practitioner's quiz"—should obviously be excluded; fortunately it is rare for an epileptic to apply. Those with anxiety conditions and other psychological disturbances are also best rejected. Doctors generally drive cars themselves, but it is necessary to remember that the continuous driving of a heavy vehicle is a different proposition. The highest degree of clinical acumen is needed for these examinations, not only in obtaining a sufficiently accurate history but also in the use of that despised instrument the stethoscope.

Having emerged triumphant from his interview, test drive, and careful clinical examination, the would-be driver enters upon a period of training—and the thoroughness of this is also a vital safety factor. Once drivers are in service it is the practice to follow up their records and performance on the roads, a particularly valuable indication during the initial months of service. Many undertakings take advantage of the scheme under which the Royal Society for the Prevention of Accidents gives "safety first" awards for years of freedom from blame-worthy accidents; these awards are the pride of the drivers and provide an incentive for safety.

Methods of psychological testing for accident-proneness have been developed in the United States and some Continental countries. These tests are numerous and include reaction-time, mechanical aptitude, co-ordination, vigilance, and speed judgment tests; intelligence tests are sometimes given, but good drivers are not necessarily good with paper and pencil. Their value has yet to be proved, and they are not at present in general use in this country. If, however, it could be shown that by means of the tests the exclusion of, say, 10% of applicants would result in a 20%—or greater—reduction in the number of accidents there would be

a good case for their introduction. A recent contribution to the subject is that of Brandaleone and Daily,² who describe the methods of selection used by the Third Avenue Transit Company of New York—personnel tests, medical, "motorability," and psychophysical examinations. These tests were introduced about three years ago, and in the case of 40 drivers they are reported as having reduced the accident rate by 40% over a 24-month period. Unfortunately, it is not stated what tests were in use before the new procedures were introduced, and clearly the more detailed assessment of a larger number of men over a longer period is required before a final assessment can be made. The present methods of selection of bus drivers used in this country appears to be giving satisfactory results, and in all this the drivers themselves deserve a measure of congratulation. They are a fine body of men.

CLOSER LINK

Of the many reports and memoranda on the association between general practitioners and hospitals published since the Health Service began, all emphasize the need for this relationship to be much closer than it is. Administratively it includes access to hospital beds where the family doctor may treat his patients, and the use of certain services obtainable only at hospitals, such as those for having radiographic examinations and pathological tests done. A less tangible feature of the relationship is that general practitioners should be welcomed in hospital wards and out-patient departments instead of, as they sometimes are, regarded as interlopers. While no dissentient voices have been raised against the principle, in individual instances reasons have been found time and again for filching a particular group of hospital beds from the care of general practitioners or for so altering hospital staffs that there is no place for general practitioners on them. Though some of these changes may have been for the good of the medical services, by no means all have been.

The Scottish Health Services Council¹ has now joined with the rest in pointing out that "there is an obvious need for a closer link between the general practitioner and the hospital and specialist services." And the committee that prepared the report had evidence of a prevalent feeling that hospital work is becoming almost exclusively the sphere of the specialist and the hospitals themselves a preserve where the general practitioner is neither needed nor welcomed. The creation of this "antiseptic barrier" dividing clinical doctors into two isolated groups is deplored by those who work on either side of it. Yet few would doubt that much needs to be done if hospital and family doctors are to be united in their efforts to treat not merely the same diseases but the same patients. Doctors abroad often look askance at how the general practitioner in Britain is, as they see it, cut off from the hospitals in his area, and are astonished to find that often enough he does not work in any hospital.

One of the main reasons why a much closer association is needed than at present exists is given towards the

end of the Scottish report: it states that the general hospital ought to be a centre of medical endeavour where general practitioners have the acknowledged right of entry and where they can meet their hospital colleagues on terms of equality. All would agree that such close association would broaden the outlook of doctors in both branches of the profession. Clinical assistantships already exist in a number of hospitals, but the Scottish report rightly goes further in advocating that the hospital structure should include a certain number of doctors engaged partly in general and partly in specialist practice. An incidental benefit of this arrangement would be that medical students could receive some of their training from general practitioners.

Once again the need for putting beds in the care of general practitioners is emphasized. Many patients admitted to hospital are suffering from conditions which their own family doctor can treat—and often does treat in the patients' homes. It is a waste of money for these patients to be treated by specialists, and admission to hospital is a break in the continuity of medical care which, however necessary sometimes, must always to a certain extent be regrettable. Again, Avery Jones has pointed out³ that "much of the present work of hospital out-patient departments properly belongs to general practitioners."

It is to be hoped that this report will not merely be welcomed (as it deserves to be) and then left to gather dust until covered with other reports saying the same thing. The frustration to which many general practitioners bear witness is largely due to their finding it difficult to practise clinical medicine in its fullest sense. Doctors whose work lies entirely or mainly in hospitals agree on the value of consultation with the family doctor. The report indicates how these problems might be solved, but it was nearly two years ago that the Council of the B.M.A. did likewise.³ That report also drew attention to the fact that closer contact with hospitals would enable the general practitioner to give better service to his patients, and "the knowledge of the personal and human aspect of patients in which the general practitioner is so well versed can be of enormous value in hospital treatment." If the medical services are allowed to continue to fall apart, as they will do if these warnings are not heeded, they will soon deteriorate.

STREPTOMYCIN IN OPHTHALMOLOGY

Since 1944, when streptomycin was first isolated, there has been considerable research on its use against the tubercle bacillus and against Gram-negative bacilli, neither of which are inhibited by penicillin. In ophthalmic work certain diseases are considered clinically to be tuberculous, but often without pathological or bacteriological proof, so that treatment by streptomycin in such cases may be said to be experimental. There are disadvantages in its use: bacteria quickly become resistant to it, and patients develop toxic symp-

³ *British Medical Journal Supplement*, April 22, 1950, p. 165.

toms (nausea, skin rashes, and sometimes an affection of the eighth nerve, causing deafness and vertigo). The paper by Professor Sorsby and his colleagues (p. 119) is an interesting and instructive account of cases treated over the last three years, considered in four groups—those with definite bacteriological or histological findings, those presumed tuberculous on clinical grounds, those so presumed on indefinite grounds, and cases of tuberculous allergy. As the authors point out, most eye diseases supposed to be tuberculous are considered to be part of a general infection, so that local treatment alone could hardly be expected to be effective. On the other hand, in diseases due to Gram-negative bacilli local therapy alone should be successful.

In fact Sorsby's results show that acute conjunctivitis, and that type of corneal ulcer which is associated with Gram-negative bacilli, respond remarkably well to local treatment. In acute conjunctivitis it is sufficient to use drops (0.5 g. per ml.). But in cases with corneal involvement subconjunctival injection is the method of choice. The authors stress the point that the injection is more effective if given in adrenaline, which must be fresh. They found that subconjunctival injection is very well tolerated, and the dose recommended is 0.5 g. in 1 ml. fluid. (Each 10 minims of fluid has 5 minims 1/1,000 adrenaline added to it.) In tuberculous keratitis results were good in the three cases quoted. Streptomycin was given intramuscularly (2 g. to 5 g. daily for one or two months). In Eales's disease and in iridocyclitis clinically suggestive of a tuberculous origin results were not so good. In phlyctenular disease there are possibilities of improving cases which relapse often or do not respond to the sanatorium regime. An important fact that emerges is that only cases of proved tuberculosis can be expected to respond to streptomycin.

It is clear that success can be guaranteed in infective keratitis due to Gram-negative bacilli, but early treatment is essential to avoid corneal scars. If the diagnosis cannot be made clinically a culture should be taken at the outset of the treatment—otherwise the patient may waste valuable days using penicillin, which will do no good.

The results obtained and quoted in this paper bear out the statement made by Duke Elder and Goldsmith¹ that in ophthalmology the efficacy of streptomycin is restricted to superficial infections with Gram-negative bacilli, proved tuberculosis, and tularaemia.

B.M.A. FILM CATALOGUE

For several years the B.M.A. Film Library has been collecting a wide variety of films; it is now the largest in Britain, and contains over 200. The publication of a catalogue listing these films is therefore timely and should be of great use to B.M.A. Branches and Divisions for their meetings, to medical schools, and to other organizations. The films are clearly indexed under subjects and alphabetically, and the notes on each include a synopsis of what is shown, the author of the material,

and such technical details as size, running time, and whether silent or with spoken commentary.

The value of films in medical education is beyond dispute, provided they are well chosen and presented with a suitable introduction or commentary when necessary. Experiment on how to get the most out of films has still to be carried further. Steinberg and Lewis² have indicated how to extend this research and have given some experimental results on teaching medical students. But there is no doubt that the present use of instructional films should be greater than it is, and anyone perusing this catalogue will be surprised at the variety of medical and surgical techniques now illustrated by acknowledged authorities. In order to maintain a high standard, the library has had every film appraised by experts for its educational value before listing it in the catalogue, and the same care has been exercised before obtaining a film for the library. The Film Committee has performed a useful service in setting out its wares so attractively in the catalogue, which may be obtained for 5s. from B.M.A. House, Tavistock Square, London, W.C.1.

"WEST INDIAN MEDICAL JOURNAL"

In spite of all kinds of difficulties, such as the explosion which recently wrecked laboratories at Makerere College and the hurricane which earlier swept across Jamaica, the new medical schools in the Colonies are making important progress. This is particularly true of the new University College of the West Indies, which has just produced the first issue of the *West Indian Medical Journal*³ under the guiding hand of the Professor of Pathology. The journal is the offspring of the short-lived *Jamaica Medical Review*, and contains contributions from members of the Government medical services in the Caribbean as well as from the various departments of the Faculty of Medicine. Some of the articles are useful reviews (e.g., "What is Kwashiorkor?"), while others discuss the peculiarities of disease in the region, or describe scientific research in progress.

The Caribbean is a vast area, about 2,000 miles across from east to west and half as much from north to south, with about 3,000,000 inhabitants mostly scattered on small islands separated by immense stretches of sea. The aeroplane is the standard method of travel. Recently the Caribbean Council of the B.M.A., representing 425 doctors in the area, was meeting in Kingston to discuss the unification of medical services. The time is thus ripe for collaborative studies on the spread of epidemics, and the comparison of pathological processes on different islands and among the different races. The West Indies may prove to be an important natural laboratory for medical study, and with the new Faculty of Medicine at St. Andrew to lead the way results of international importance are likely to be obtained. The new journal will be there to carry them across the world.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

PARKINSONISM

BY

HUGH G. GARLAND, M.D., F.R.C.P.

Physician in Charge, Department of Neurology, General Infirmary at Leeds

As is true of morbidity in general, we know little of the incidence of Parkinsonism in Great Britain, but with the kind co-operation of a group of practitioners in the Leeds area it has been possible to gain an approximate idea of it.

Incidence of Parkinsonism in Leeds and District

Population surveyed		485,903
Parkinsonism (all forms)		288
Approximate incidence		1 in 1,700
Approximate total in Great Britain		27,000

These figures may not be strictly accurate, but they probably represent the minimal incidence of Parkinsonism in the population. In the same survey the incidence of disseminated sclerosis was almost precisely the same—282 patients.

Aetiology

The aetiology of Parkinsonism is probably always complex. Paralysis agitans, originally described by Parkinson in 1817, is a degenerative disorder, or abiotrophy of the extrapyramidal system, particularly of the corpus striatum and substantia nigra. Recent Scandinavian work suggests that there is a genetic factor in its production, but other factors have to be considered. Parkinsonism not infrequently first appears after a single head injury or following the multiple injuries of a boxer, and all neurologists are familiar with the sudden appearance of Parkinsonism after some form of emotional stress, such as is occasioned by accidents in which there was no serious physical trauma. These factors, difficult to assess, are of considerable importance in medico-legal work, but unfortunately it is rarely possible to be quite certain whether the Parkinsonism was already present before the accident or other incident. Most neurologists will have had the experience of discovering the earliest evidence of Parkinsonism in a patient being examined for some unrelated condition, who at the time of examination has no symptoms referable to his signs. As with so many other chronic, progressive, and degenerative disorders, there is an increasing tendency to take the view that paralysis agitans may be essentially a psychosomatic disorder: there are those who claim that a disordered personality precedes the physical disease, suggesting that people of drive and ambition, contained within a rigid moral framework, may develop paralysis agitans as a result of frustration. Age is certainly an important factor, and paralysis agitans is essentially a disorder of middle and later life, the sexes being affected equally.

An approximate aetiological classification is shown in the following Table, which is an analysis of 90 personal examples.

Aetiological Classification

Paralysis agitans		57%
Post-encephalitic		32%
Arteriosclerotic		4%
Syphilitic		2%
Doubtful		5%

The commonest variety of Parkinsonism is the "idiopathic" degeneration, paralysis agitans. The second commonest is that which follows encephalitis lethargica. This curious infection, thought, though not proved, to be a virus disease, spread rapidly over the world in epidemic waves from 1917 to 1925. There is some controversy concerning its existence before or after these dates, but there is no argument that it was only during this period that the disease existed on a massive scale. A considerable number of those who did not succumb to the acute phase developed Parkinsonism immediately, but in others the syndrome appeared many years later; the longest interval in my experience is 27 years, and presumably this is not the maximum figure. Much less commonly is Parkinsonism attributed to cerebral arteriosclerosis, with or without hypertension. Examples have also been reported as the result of carbon monoxide and of manganese poisoning. Very occasionally the syndrome arises in a patient with serological evidence of neurosyphilis.

It is by no means always easy to assign any one patient to a particular aetiological group, and indeed there are some who believe this always to be impossible; but certain features discussed below seem to be the prerogative of the post-encephalitic state, and when these appear the diagnosis of post-encephalitic Parkinsonism can be made with confidence, even though there is no history of the acute illness; indeed, such a history is now a rarity.

Signs and Symptoms

All practitioners and many laymen are familiar with the picture of advanced Parkinsonism: the monotonous and failing voice, the expressionless face with lack of blinking, the general attitude of flexion, the tremor, which is usually asymmetrical, and the general absence of the small and repeated movements of the normal person. In its earliest stages, however, the diagnosis is difficult, particularly in the absence of tremor. The attention of the patient may be first attracted by an alteration in the handwriting, which becomes smaller and less legible. At this stage he will also notice difficulty in carrying out the finer and more skilled movements of the fingers, such as those in playing the piano. It is only rarely that disability is first noticed in the legs. On questioning, at any stage, the patient will realize in retrospect that there has been a general slowing down of all physical activity over the previous months. The tremor is familiar and characteristic, and it is rarely mistaken for anything else, but in the absence of tremor the disability, which is often limited to one arm, may be attributed to a wide variety of neurological disorders. It is only for the latter reason that early diagnosis is important so as to prevent the patient from being subjected to lumbar puncture and even more unpleasant investigations.

Among the earliest physical signs are those involving the eyes. These consist of blepharoclonus on lightly closing the lids, weakness or paralysis of convergence,

and infrequent or absent blinking except on tapping the glabella. This latter is perhaps the most constant and certainly the most characteristic sign: On tapping the glabella both eyelids blink in time with the tapping, whether this be slow or fast, and this blinking will continue indefinitely; the normal person will only blink after the first few taps. For all practical purposes this physical sign is diagnostic of the Parkinsonian state.

Oculogyric crises are highly characteristic and are pathognomonic of the post-encephalitic state. They are becoming increasingly rare. During the crisis the two eyes are suddenly turned, usually upwards, though occasionally to one side. They may turn so far up that the patient cannot see at all, and they may maintain this position for minutes or hours, and in the latter case the eyes may become painful. The attacks occur with varying frequency, but at the worst may appear every day and last for several hours. They are frequently precipitated by psychological factors. These crises are often the presenting symptom of Parkinsonism, but there are always associated eye signs and frequently other evidence of Parkinsonism, though occasionally there may be no involvement of the limbs.

Rigidity is often first detectable in the neck, a place in which it is rarely sought. After the neck the most common site for rigidity is at the wrist, and here the characteristic "cog-wheel" element is elicited by frequent passive flexion and extension of the joint. This is a most important physical sign, and it varies considerably, even from minute to minute in the earlier stages of the disease. Later, similar rigidity is constantly present at all joints, though it is always more obvious at the periphery. A tendency to propulsion or retropulsion is usually a late sign, only demonstrable when the diagnosis is all too obvious. It is important to remember that Parkinsonism, though often bilateral, is usually asymmetrical, and in many patients it is strictly unilateral for very long periods. In a considerable number tremor never appears, nor is it ever seen in the absence of the characteristic rigidity. Though often asymmetrical in the limbs, involvement of the eyes and facial muscles is always bilateral and symmetrical.

In the well-established case, but probably never as a presenting symptom, excessive salivation is frequent, particularly in the post-encephalitic patient, in whom the skin is often very greasy. To the Parkinsonian every movement is an effort, and it is usually easier for him to sit quite still than to move about; some, however, have a feeling of restlessness and an anxiety to move about, which is a practical impossibility. Not infrequently there is a complaint of pain or discomfort in the joints of the affected limbs, and stiffness or ankylosis is apt to appear in the shoulder-joints.

Apart from any question of psychogenesis, there are very important psychological aspects of the established disease. The patient finds himself living in a continuously contracting environment, in which he becomes more and more dependent on other members of the family, and small worries and problems assume unduly large proportions. Immediate emotional factors adversely affect all the signs and symptoms of the disorder—an observation usually made by every sufferer.

Prognosis

Parkinsonism is an irreversible process, and no patient has ever been cured. A small proportion of post-encephalitic cases become stationary for very long

periods, and perhaps indefinitely, but all other forms of Parkinsonism are inevitably progressive sooner or later, though often with stationary phases. The rate of progress is extremely variable, but it is usually many years before the patient becomes bedridden.

Medical Treatment

Drugs of the solanaceous-group have been used for over 80 years. It was pointed out about 1929, mainly by the late Sir Arthur Hall, that these drugs are most effective when given in increasing dosage up to the point at which toxic symptoms appear. This dosage is sometimes enormous; for example, the normal dose of tincture of stramonium (5 to 15 min.—0.3 to 0.9 ml.) can be increased to 100 min. (6 ml.) three times a day or even more. Tolerance has to be acquired slowly, but is lost very rapidly. If for any reason a patient who has been taking maximal doses suddenly omits his treatment it is essential that tolerance shall again be acquired slowly, otherwise serious toxic symptoms make their appearance. Occasionally when a patient omits to take his treatment a Parkinsonian crisis is precipitated, and he becomes totally rigid and immobile. This rare but alarming state of affairs soon responds to a renewal of drug treatment.

When large doses of the belladonna group are being taken there is always complaint of difficulty in reading, owing to paralysis of accommodation, and of dryness of the mouth; these can respectively be relieved by eserine drops and by adding pilocarpine nitrate to the mixture. At this point, however, medicinal treatment has become complicated, and in my experience very few patients acquire tolerance for such very large doses and then maintain them. This may well be because in the course of time drugs which at first help later become ineffective. A group of chronic Parkinsonian patients have recently been discovered, in a hospital for the chronic sick, who had been taking large doses of these drugs for many years; treatment was suddenly withdrawn, apparently with no detrimental effect. The drugs of the solanaceous group, in the approximate order of popularity, are stramonium, hyoscine, belladonna, and hyoscyamus.

About 1935 "Bulgarian belladonna" had a phase of popularity, though there was no evidence that it was, in fact, any more effective than other members of the group. The effect of these drugs is usually to give the patient a feeling of increased activity and of lessening stiffness. It is doubtful whether any of them really affect the tremor, although it has been temporarily abolished by intravenous hyoscine and other drugs. Little is really known about the mechanisms of tremor, and it has been suggested that rigidity may in some way hold tremor in check; at the same time it is only very rarely that a patient will claim that his rigidity has lessened and his tremor increased. The prolonged use of any of these drugs over a number of years carries with it the risk of chronic glaucoma.

Curare was tried about 1927, but was soon abandoned. Mephanesin ("myanesin") has been in use since 1947; it is usually given in the form of an elixir, the initial dose being 1 dr. (3.5 ml.) three times a day, which can be increased up to 4 dr. (14 ml.) taken four or five times a day. The larger doses should be well diluted with water. As with most other drugs, mephanesin may reduce the rigidity but is not likely to affect the tremor and on the whole it has not been very popular.

Numerous synthetic drugs have been introduced for the treatment of Parkinsonism in the past few years, and the list is steadily increasing. As with the solanaceous group, all these drugs are preferably given by mouth in increasing dosage until toxic symptoms appear, and it is still important that the dosage should be increased or decreased slowly. Any of these drugs may be combined with one of the solanaceous group. The general feeling is that the new drugs are perhaps more effective than the old, and they certainly seem to produce effects more quickly.

Perhaps the most popular at the time of writing is trihexyphenidyl ("artane"), which has a pharmacological action similar to that of atropine. The initial dose is 1 mg. on the first day, increased by 1 or 2 mg. daily up to a total of about 12 mg. divided into three or four doses. Toxic symptoms may appear at or before this level, though some patients will take as much as 15 mg. and very rarely 20 mg. daily. The toxic symptoms include dryness of the mouth, nausea, dizziness, and, less commonly, blurring of vision. This drug again may produce apparent relief of rigidity and sometimes reduces salivation, though it does not appear to relieve the salivation of the post-encephalitic; its effect on tremor is very questionable.

Ethopropazine hydrochloride ("lysivane") is supplied in orange-coloured tablets containing 50 mg. of the drug, the initial dose being 50 to 200 mg., which can be steadily increased up to 500 mg. over a period of three to four weeks. Side-effects include drowsiness and dizziness, nausea, paraesthesiae, and cramp in the limbs.

"Parpanit" is supplied in tablets of two strengths, the smaller containing 6.25 mg. and the larger (parpanit forte) containing 50 mg. It is usual to start with six small tablets daily (two tablets three times a day), increasing up to a maximum of about 24 tablets a day (one large tablet is the equivalent of eight small ones). Toxic symptoms again include dizziness as well as palpitation and tinnitus.

Diethazine hydrochloride ("diparcol") has now been largely abandoned, because toxic symptoms have included mental confusion and agranulocytosis.

As with the older drugs, it is unusual to find a patient who is prepared to take the trouble to acquire tolerance for a high dosage and to maintain it. The more usual state of affairs is to find that the patient has of his own accord made a considerable reduction in the total dosage. It would often seem likely that the finally accepted dosage is not much more than a placebo. It has also been found that the antihistamine drugs sometimes benefit the rigidity and general slowness. The usual practice is to combine these drugs with one of the previously named preparations. When large doses of these new drugs are given in combination over a long period it is possible, and indeed highly likely, that toxic symptoms will appear which have not yet been described. The antihistamine drugs tend to produce drowsiness and are sometimes better limited to an evening dose only.

Oculogyric crises never respond to any of the above-mentioned drugs, though their frequency is sometimes lessened under the continuous action of amphetamine. If attacks are very frequent and prolonged, electric convulsion therapy is worthy of trial and in my experience has often proved effective. In the very rare Parkinsonian who has serological evidence of neurosyphilis antisyphilitic treatment must be instituted, but it will not be found to reverse the Parkinsonian syndrome.

Physiotherapy is probably as important as medicinal treatment. The essential part of physiotherapy is vigorous active exercises employing all four limbs, and in the very advanced Parkinsonian daily passive movements of all joints are essential. Hot baths will often relieve the disability in the joints and to some extent the general stiffness. Massage, all forms of electricity, and all emanations have no particular therapeutic value in this disease.

The psychological aspects of treatment have to be left largely in the hands of the family. There is a natural tendency to pay too much attention to the Parkinsonian, who should in fact be given every encouragement to remain at work as long as possible and to fend for himself in the house. At the other end of the scale, and particularly in the early stages before the diagnosis has been established, the patient is sometimes accused of idleness, and I have seen a case in which a nagging wife was murdered by the infuriated patient.

Surgery in Parkinsonism

The position of surgery is at present unsettled, and publicity in the lay press has often been quite irresponsible. Surgical procedures aim at abolishing tremor and replacing it by weakness or paralysis, and operations may be performed either on the cerebral cortex or on the spinal cord. Since most cases of Parkinsonism are progressive careful selection of patients for surgery is vital. Surgery should probably be limited to patients under 50 who are suffering from gross tremor which is stationary or only slightly progressive and is restricted to one arm. Such rules will exclude about 95% of all patients. It has been claimed that in the ideal case tremor can be abolished, and that the resulting paralysis is not complete, but no such guarantee can be made. I have seen a patient with a post-encephalitic tremor limited to the left hand and stationary for many years who was still able to work and to play golf and tennis; after an operation on the cerebral cortex the tremor disappeared, only to be replaced by a total left hemiplegia and Jacksonian epilepsy, with very serious and permanent disability. Operative mortality figures seem never to be lower than 17%, rising to 35% in those above the age of 50.

In assessing the value of any form of treatment in Parkinsonism it must be remembered that it has always been known that a new remedy is likely to achieve results at first, but that such benefit rarely lasts. This is not surprising, because the patient who claims to feel much better as a result of medicinal treatment rarely shows any striking objective change. It is not suggested that large doses of powerful drugs have, in fact, no beneficial pharmacological action, but there seems little doubt that much of the alleged benefit is the result of suggestion. The optimism caused by early improvement is soon replaced by dejection following relapse, and this is reflected in an attitude of hostility and resentment to the doctor—often very obvious in the patient's face. Because of the factor of suggestion, and the natural tendency of the disease to have stationary phases, the assessment of treatment is as difficult as it is with such diseases as peptic ulcer, rheumatoid arthritis, or ulcerative colitis, although, unlike these, Parkinsonism never shows phases of remission.

Finally, the Parkinsonian must be encouraged to maintain his physical and mental activities and to take an interest in the nature and dosage of the large variety of drugs available to relieve his symptoms.

RECENT HISTORY OF PNEUMONIA

OSLER CLUB SYMPOSIUM

The 99th meeting of the Osler Club, held in London on January 11, with Mr. ZACHARY COPE in the chair, was devoted to a symposium on pneumonia in Osler's time and since.

Osler's Fatal Illness

LORD HORDER began by giving an intimate and moving account of Osler's fatal illness. He said that when Harvey Cushing's *Life of Osler* appeared in 1925 he was disappointed to find that in the last few poignant pages the drama of the final stage of Osler's illness had been telescoped into a few apparently casual references. It was on December 12, 1919, that Osler, who was suffering from a prolonged and obscure disease in his chest, sent for him to come to Oxford. It was a shock to see him very ill and emaciated, in a state of extreme toxæmia, and speaking little because speech brought on a bout of paroxysmal coughing. Osler himself had jotted down for his information, in that terse fashion of his, some pencilled comments on his own condition. Seven days previously the chest had been punctured and a little serous fluid drawn off without any relief of symptoms. Lord Horder postulated the presence of an interlobar empyema, and the puncture was repeated, using the longest needle procurable at the time. The same sort of fluid was forthcoming and that only in small amount. The condition remained relatively unchanged for another week, so that he made up his mind that something further should be done by way of exploration. A couple of extra long needles were made, Osler readily agreeing to the exploratory "séance." The first puncture was negative, but the second was successful, and when the stylet was withdrawn Osler himself said, "You've got it, my boy." Between 4 and 5 ml. of stinking pus was withdrawn. On the following day Charles Gordon-Watson drained an abscess cavity. The drainage, never very copious, ceased three days later. No further collection of pus was revealed by a second operation. Four days later the end came in dramatic fashion. He (Lord Horder) had talked with Osler in the morning, and had then gone to lunch downstairs, when the nurse called him quickly, and on going upstairs he found that the dressings and the bed were soaked in blood. The sepsis had opened up the wall of a small vessel in the upper lobe of the lung, and Osler died a few hours later that day.

A study of Osler's last illness threw little if any light on the subject of pneumonia in general. The fact that the pus contained Pfeiffer's bacillus was no more proof that the original disease was an "influenzal pneumonia" than the fact that the onset of the disease occurred during a period of fairly high influenzal incidence. All that could be said was that the disease might well have come into the category of what was to-day called "atypical or virus pneumonia," an unfortunate introduction into the nomenclature. Nor did he much favour the term "pneumonitis," though there was more to be said for it. Even in a severe epidemic of influenza it was more helpful to label the condition "influenza with pneumonia" than to call it "influenzal pneumonia." The critic might ask what a name mattered, but it did matter how words were used, because words determined subsequent thinking. The tendency to stress the lung condition so as to give it a predominant place in the nomenclature was probably due to the fact that, both clinically and histologically, the lung lesions declared themselves while yet the search went on for causative agents in the great majority of virus infections. This tendency should be resisted. With more research and some forbearance the answer would be unfolded.

As long ago as 1887, in an editorial summary of a report on pneumonia in the hospitals of New York and Boston, Osler said that the disease had come to be known as a specifically self-limited disease, and the only rational treatment was the expectant one. He added, however, that to the next generation the symptomatic and expectant plan of treatment then in vogue would appear crude and

unscientific. Osler's prophecy had been fulfilled, and so no doubt would be a further prophecy that the generation next to ours would regard as crude and unscientific the nosology at present used with respect to pneumonias in the textbooks to-day.

The Advent of the Sulphonamides

Sir LIONEL WHITBY followed with a succinct account of the discovery by Domagk and his assistants at Elberfeld of the anti-streptococcal activity of an azo dye containing a sulphonamide group. Domagk's compound, known as "prontosil," was patented in 1932, but the experimental results were not published until 1935, and these were followed by clinical reports in German literature concerning work which had been going on in the trial period. Prontosil was a water-insoluble basic azo dye (sulphamido-chrysoidin) suitable for oral administration, from which an acid dye known as prontosil soluble was developed. It was early suggested and later proved that this complex molecule of sulphamido-chrysoidin owed most of its virtue to the fact that it was reduced in the body to *p*-aminobenzene-sulphonamide, now known as sulphanilamide.

As a result of a great deal of research there eventually emerged so far as pneumonia was concerned, and in historical order, sulphapyridine (at first known as M. & B. 693), sulphathiazole, sulphadiazine, sulphamezathine, and sulphamerazine. The first of these was synthesized by Ewins and Phillips, of May and Baker, Ltd., and was proved to have great therapeutic value against pneumococcal infections in mice. Clinical confirmation in the human subject soon followed, first in a few cases reported by Telling and Oliver 13 years ago, and then by Evans and Gaisford, who in a Birmingham municipal hospital in that year treated 100 cases of lobar pneumonia with a mortality of no more than 8%, whereas the control series had a death-rate as high as 27%. From even this small experiment it was clear that the disease which in the days of Osler could be treated by no more than palliatives, stimulants, sedatives, and careful nursing, and later by a laborious and expensive serum routine, could now be easily and cheaply controlled.

Sir Lionel Whitby gave one or two personal anecdotal recollections of those wonderful years. It was the intrusion of a good dinner which led to the feeding of a batch of mice with sulphapyridine at a rather late and unpopular hour—indeed, well after midnight. This batch was the first to exhibit a survival rate of 100%. Thereafter in all assays the technique was so altered as to contain a night dose, and all who recalled the time when the "sulpha" drugs were used widely for the treatment of pneumonia would remember that this rule was carried out at the bedside with dosage four-hourly day and night.

Sulphapyridine was handicapped by the intense vomiting it caused, which led some who owed their lives to the drug to declare that they would prefer to die rather than endure the treatment again. Thus sulphathiazole, not much more active but far less toxic than sulphapyridine, came to replace the latter as soon as it had been rediscovered. Sulphathiazole was in actual fact found at the same time as sulphapyridine when mouse tests were being carried out, but there was a tendency to pass it over, since in the animal it seemed to have little or no advantage over sulphapyridine—a finding which was due to rapid excretion and therefore low blood concentration.

It might be said as a historical fact that the sulphonamides, from sulphapyridine to sulphamerazine, held the field for the specific treatment of pneumococcal pneumonia until penicillin came to be sufficiently plentiful for everyday use. Even to this day one or other of the potent and relatively non-toxic sulphonamides could still be regarded as an indispensable drug.

Changing Clinical Aspects

Sir ADOLPHE ABRAHAM said that he was told that the modern medical student rarely saw a case of typical lobar pneumonia. Unhappily a "superannuated physician" had had ample opportunity for such clinical observations. But

FOR THE RELIEF of bronchial asthma, a choice of 'Neo-Epinine' preparations is available. Almost immediate relief is obtainable by oral inhalation of No. 1 Spray Solution, a plain 1 per cent aqueous preparation. The 20 mgm. compressed products, placed beneath the tongue, act within 5-10 minutes. Stubborn cases need oral inhalation of No. 2 Compound Spray Solution which contains 1 per cent of drug with 2 per cent of papaverine and 0.2 per cent of atropine methonitrate.

so *this* is flavour!

The time for new taste adventures has come when a baby weighs 15 lb. Farex with honey (most babies think highly of that!) ... Farex with grated chocolate ... Farex with vegetable puree; yes, learning to accept and appreciate new tastes is certainly an important part of a baby's education, while Farex itself takes care of his growing nutritional needs. Farex is a good mixer with almost any flavour—another point worth making when explaining to mothers why Farex is not only a first-rate weaning food but a *training* food as well.

Having a word about weaning?

THE WORD IS...

FAREX

3-cereal 'training' food in 10-oz. cartons

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX BYRON 3434

The complete answer for macrocytic anæmias

Clinical experience over a decade has established that the administration of Anahæmin constitutes the most effective form of treatment for pernicious anæmia.

Anahæmin produces, with small and comparatively infrequent doses, a prompt and satisfactory erythropoiesis in patients in relapse, it ensures the maintenance of a normal erythrocyte level in patients

in remission and is effective in preventing the onset of subacute combined degeneration of the cord.

Anahæmin has also been found to be of value in the treatment of herpes zoster and post-herpetic neuralgia. The suggested dosage is 2 ml. followed by 1 ml. on subsequent days until relief is obtained.

Anah/E/117

was there in fact a remarkable reduction in the present-day incidence of lobar pneumonia? Had the type of case changed, and had the treatment by sulphonamides been responsible for the change? Then what about all this business of virus pneumonia or pneumonitis? He was not in a position to judge. "Old dogs do not learn new tricks." In his view lobar pneumonia received in many circles an entirely wrong nomenclature. He was taught—not by Lord Horder—that pneumonia was a disease of the lungs, a misconception which he had never been able to dispel. Osler rightly put pneumonia in his section of diseases due to bacterial infection; yet modern textbooks of medicine put it among the diseases of the respiratory organs. Pneumonia was no more a disease of the lungs, although respiratory symptoms predominated, than typhoid fever was a disease of the intestines.

During 2½ years in the first world war he (Sir Adolphe Abrahams) saw 558 cases of lobar pneumonia from onset to termination. In nearly every case the disease began with a rigor. Temperature was generally of the order of 102–3° F., rarely higher. The pulse-respiration ratio, upon which clinicians were very emphatic, was raised. Physical signs in 80 or 90% of the cases occurred within the first four days. Physicians with exceptional experience developed a flair for the recognition of early physical signs; they did not wait for such features as dullness at the base or even bronchial breathing, but there was a queer little catch in the breath which they recognized. In only 12 of his cases were physical signs entirely absent throughout the illness. The sputum was generally of the so-called rusty type. In something over 10% of the cases sputum was entirely absent. Other features worth mentioning were herpes, which Hippocrates had observed, and which denoted a good prognosis, abdominal pain (severe in 31 of the 558 cases), and thoracic pain (almost invariable, and not always on the same side as the physical signs, and more frequently on the right than on the left). The mortality had been 10.9%. The only complication of any real significance was empyema, the incidence of which was over 20%. Other complications were pericarditis, meningitis, arthritis occasionally, and, he supposed, infective endocarditis, but these were very few indeed.

As for prognosis, one of the features of lobar pneumonia was that some who were almost moribund recovered and sometimes a comparatively benign case running a good course suddenly collapsed and the patient died. The fact that the only treatment in those days was expectant and symptomatic did not prevent people from trying all sorts of remedies. It was a commonplace for practitioners to write to the medical journals stating that they had been in practice for 20 years and had seen 15 cases of lobar pneumonia all of which had recovered in consequence of a particular treatment. People who used vaccines produced figures which to a certain extent were convincing. In his own series he had at one time 70 consecutive cases without a death. Had he adopted some form of special treatment, the more fantastic the better, the conclusion would have been irresistible that his treatment had had something to do with it. At one time brandy was regarded as a sort of specific. On the other hand, the London Temperance Hospital then gave alcohol only to patients practically moribund, with the result, of course, that their statistics worked out very much to the detriment of alcohol. Oxygen was used, but more for the benefit of relatives than of the patient. But the treatment in those days boiled down to good nursing, fresh air (if he himself had any choice in the matter he had his patients in the open air), and, above all, sedatives to induce sleep. In his experience 70%, he thought, would have recovered whatever was done; between 20 and 30% would have died whatever was done. There remained 5 or 10% in which skilled treatment and nursing might just have turned the scale. He was always impressed by Leonard Williams's dictum that pneumonia was best treated by faith, hope, and charity—faith in *vis medicatrix naturae*, hope for the absence of complications, and charity towards those who differed from you.

Various Experiences

Sir ALEXANDER FLEMING recalled a senior physician to whom he was once clerk whose chief treatment for pneumonia was ice packs. Unfortunately, he had a junior who did not believe in ice packs and put on poultices—a confusing situation. Sir Alexander was told that they did not see pneumococcal pneumonia in hospital now. Sulphonamides and antibiotics were given outside, and the hospital got only the cases where these agents failed. The cases that came to hospital were sometimes amenable to "aureomycin" or "chloromycetin," and then they were called virus pneumonia. "I do not know what virus pneumonia is, but it is quite a nice name, anyway." Dr. W. R. THROWER, who was associated with the work in the laboratories of May and Baker, gave an account of his first case treated with "693." On May 16, 1938, he was presented with a box of the tablets and forgot about them, but two days later a case of lobar pneumonia in a man aged 45 was presented, and he decided to see what these tablets could do. It was not known how much to give, nor how often, nor how the drug acted. A very tentative start was made by giving 0.5 g. four-hourly. The dose was repeated throughout the night. The next morning the patient was no worse, perhaps better, but by the afternoon there was undoubted improvement. The following morning, which should have been the morning of crisis, the patient was sitting up and asking for food. Mr. G. H. COLT described his own experience as a patient with double pneumonia at the time of the first world war. The great help was nursing. The V.A.D. service, which produced hot meals at all hours of the day and night, helped tremendously.

Dr. ALEXANDER CAWADIAS spoke in appreciation of Lord Horder's insistence on careful nosology and upon the natural history of disease, to borrow a term from Sydenham. The natural history of pneumonia was, of course, first described by Hippocrates. One of the best descriptions in modern times was by the French nosologist Grisolle. Dr. Cawadias agreed with Lord Horder in his objection to the term "influenzal pneumonia." Influenza was in one morbid category and pneumonia in another. Concerning the history of treatment, he mentioned that meted out to an early Empress of Austria in the eighteenth century. It was reported that she had cough, sputum, and pain. The physicians were called in and bled her 3 or 4 pints. She was no better, and they bled again, 5 or 6 pints, and, as there was no improvement, they came next day and bled her again, and it was reported that "notwithstanding the active bleeding, the patient died."

Mr. DICKSON WRIGHT mentioned post-operative pneumonia, of which, he said, there were two kinds, one occurring immediately after operation and the other later. The second was the more serious in its effects. The respiration rate was high, the patient became very toxæmic, and there were mental changes.

The CHAIRMAN (Mr. Zachary Cope) mentioned that he started his career as house-physician to David Needham, who was one of the advocates of ice packs for pneumonia. Needham was a most conscientious physician, and thought there was scientific proof that the pneumococcus did not thrive so well if the temperature was a little lower than that of the body, so that the external application of an ice pack would reduce the temperature inside the chest to the required degree. It was extraordinary that so conscientious and scientific a man should adopt so pseudo-scientific an attitude. Post-operative pneumonia used to be attributed to the anaesthesia, but that was a misplaced judgment, because it had been proved again and again that pneumonia developed even after a local analgesic, when there was no infiltration of any substance into the lungs and the operation did not interfere in any way with the diaphragm.

Mr. Cope added that there were two or three medical evenings which were indelibly imprinted on his memory, and to these would be added the meeting of that evening, with the three brilliant opening addresses, the first of them, full of clinical wisdom, by a man who had just celebrated his 81st birthday. He wondered what Osler himself would

have said had he listened to Lord Horder in view of his own comment on the "usefulness of men above 60 years of age."

It was announced that Dr. Carlyle Lyon had presented the Club with certain books, including a volume of the *British Medical Journal* for 1886 which contained some of Osler's earliest writings, his Cartwright lectures on the blood corpuscles.

MEDICINE IN UGANDA

[FROM A SPECIAL CORRESPONDENT]

The annual clinical conference of the Uganda Branch of the B.M.A., held from December 7 to 9, 1951, in the Makerere Medical School at Mulago Hospital, by courtesy of the dean, was attended by many Uganda members, by representatives from Kenya and Tanganyika, and by visitors from the United Kingdom. The president of the branch, Dr. A. W. WILLIAMS, opened the proceedings with an account of the history of Mulago Hospital and the growth of the medical school.

History of the Hospital and Medical School

The Government hospital at Mulago, founded in 1913 as a venereal diseases treatment centre, had grown from a collection of mud-and-wattle grass-roofed wards to a 650-bed general hospital, accommodated in pavilion-type wards spreading down the slope of the hill. Proposals for new buildings had twice come to nothing, in 1939 and in 1946, but within the last few months a site had been cleared on which it was hoped a new hospital would be built.

The medical school, which had begun as a departmental training school of the Uganda Government, had admitted its first four students in 1924 under the first medical tutor, H. B. Owen, later principal of the school and medical superintendent of Mulago Hospital. Students from outside Uganda had been admitted in 1930. The course, at first lasting only four years, including premedical studies, without anatomical dissection, midwifery, preventive medicine, or more than the most rudimentary pathology, had developed by stages to a seven-year course with a content similar in all respects to those given in the medical schools of Great Britain. It catered now for students from Kenya, Uganda, Tanganyika, Zanzibar, and Nyasaland, who, on qualifying as holders of the Diploma of Medicine of Makerere College, became medical practitioners licensed to practise in East Africa. Well-equipped preclinical departments and a fine medical library had grown up, and there were now vigorous clinical and pathological departments at Mulago Hospital staffed jointly by members of the Colonial Medical Service and of the Makerere College clinical departments.

In tracing the growth of the hospital and school, Dr. Williams paid tribute to Uganda's voluntary hospital at Mengo and its staff, who under the late Sir Albert Cook had pioneered Western medicine in East Africa; and emphasized the indebtedness of the school to the many Colonial Service medical officers, pathologists, and specialists who had served at Mulago in the last 35 years.

Sir HENEAGE OGILVIE then spoke on the surgeon's part in the fight against cancer, and discussed the place of radiotherapy and chemotherapy in the treatment of malignant disease. In answer to a question whether East Africa should press for a radiotherapy centre, he said that the cost would be high and that he felt that the money could be more usefully spent in other ways.

The president of the Uganda Branch then opened an exhibition prepared by the major pharmaceutical and medical supply firms, the first seen in Uganda, and one which was very much appreciated by those present.

Indolence or Illness?

A discussion took place on "What are the economically important diseases of Uganda?" Dr. J. M. CALDWELL gave some figures compiled from the returns made by the larger employing concerns in Uganda, and dealt especially with malaria, respiratory disease, tropical ulcer, and injuries

as causes of loss of working hours. Tropical ulcer was a disease of the agriculturist, and in such folk correlated closely with the figures for total injuries, but this was not seen in factory workers. It was regrettable that the largest employer in Uganda, the Government, made no returns. Dr. Caldwell stressed the great importance of respiratory diseases and malaria as causes of morbidity, and Dr. R. G. LADKIN supported this by an analysis of the causes of morbidity in persons attending rural dispensaries in the regions round Kampala. The analysis covered over 250,000 out-patients. He pointed out that attendance at rural dispensaries was the nearest thing to a general-practitioner service available to Africans in Uganda. Although malaria (165/647) was the most frequent cause of admission to beds, in dispensaries it was closely followed by pneumonia (159/647), and as a cause of attendance respiratory diseases far out-topped malaria. Injuries, local infections, and surgical emergencies were the next most frequent conditions, followed by diarrhoea and dysentery, burns, pyomyositis, and gonorrhoea (all in the region of 15-45/647). Arthritis, whooping-cough, and tropical ulcer were the remaining major causes of invalidism. Dr. Ladkin then analysed the factors contributing to the high incidence of pneumonia, and concluded that the incidence was low in sparsely populated rural areas, increased considerably in areas of higher population density, and occurred in epidemic forms in overcrowded areas. It was one of the most important diseases of Uganda.

Mr. PAKENHAM-WALSH, of the Uganda Company, speaking as an employer of African labour, expressed the view that all this information hardly concerned an employer of unskilled African labour. Disease was not a cause of low production. Too much emphasis was now placed on the need to raise the standard of health and living in order to obtain a greater output per day. Since the war, conditions of health, housing, and food had improved and absenteeism had been reduced, but work output had actually fallen. By custom, agricultural work ceased at noon or when the task appropriate to such working hours was completed, and, while disease might make a man slow in completing his task, the healthy man did no more. In a labour force of 850 men in the last 12 months absenteeism from sickness was only 0.9% and absenteeism from other causes was only 1.9% as against 30% before the war, when no food was issued. The more serious diseases of Uganda were indolence, established custom, and lack of economic pressure.

An animated discussion followed these papers. The question of incentives was raised, and one suggestion for reducing invalidism was the supply of cheap waterproof clothing. Mr. Pakenham-Walsh's experience was supported by many present.

The Absence of "Stress" Diseases

On the following morning a clinic was held by the staff of the medical division of the hospital. Cases were shown by Dr. A. W. Williams, Dr. P. W. Hutton, Dr. A. B. Raper, and Dr. H. C. Trowell.

Dr. J. H. SHELDON then described his experiences with A.C.T.H. and cortisone in clinical medicine, and went on to discuss their relevance to local conditions. He was fascinated by the fact that all the diseases for which they were frequently used, in temperate regions, rheumatoid arthritis particularly, were absent or very rare in Uganda. He hoped that research would be directed to the elucidation of the problems presented by this disparity. It seemed that the African response to stress was abnormal; or was it normal and the European reaction abnormal? Did diet play a part? It seemed possible that a deficient diet might not provide the necessary materials for the elaboration of steroid hormones and that the frequency of enlarged adrenal glands in Africans was an indication of an attempt to make good this failure.

Epidemiology of Schistosomiasis in the West Nile District

Dr. G. NELSON then described his survey of schistosomiasis (Mansoni) in the West Nile district, where the

Nile leaves Lake Albert and meanders on its way to the Sudan. The results of large surveys suggested that the infestation was spreading downstream from the lake. The incidence in children in the upper reaches was extraordinarily high, but the effects seemed minimal, and he considered that increasing malnutrition due to extended use of the protein-poor cassava was a much more important source of ill-health. He had found evidence of periodicity: in regions where there had been a high incidence in previous years the incidence was now much less. The infestation caused little apparent effect, save perhaps in children; the incidence of anaemia, splenomegaly, and abdominal symptoms was no greater in infested patients than in those uninfested. He presented in many maps and tables the results of this survey.

In the subsequent discussion Dr. LADKIN suggested that poor rainfall, resulting in unflushed pools, might account for the spread of the disease rather than the dispersal of infected snails on floating vegetation in the Nile. He described the failure of the rains in 1942-3 with consequent famine in the area, which, he thought, might have upset the ecological balance and led to spread of infestation. He agreed that cassava was a greater menace than the schistosome. Dr. Ladkin's views were supported by several speakers, but no one could explain how pools teeming with snails one week could be so free of snails one week later and in the absence of flushing. Dr. Nelson's comments on the absence of signs and symptoms due to *Schistosoma mansoni* infestation received wide support.

Uterine Tone and Pregnancy Anaemia

Professor W. C. W. NIXON then discussed the problem of abnormal uterine activity in labour, illustrating his points with records of the uterine contractions, including some taken during his visit to Uganda. He dwelt on the relevance of this work to local conditions where difficult labours and rupture of the uterus were frequently seen, and he speculated on the cause of the hypertonicity he had found in the African uterus.

Dr. J. M. VAIZEY then discussed some 66 cases of anaemia in pregnancy studied in Eastern Uganda. By European standards all the 2,020 pregnant women studied were anaemic, but he had made a special study of a group with haemoglobin levels of less than 6 g./100 ml. Most of these showed a macrocytic hypochromic anaemia which responded to good food and iron, with deworming if there was ankylostomiasis. But neither helminthic infestation nor malaria accounted for more than a small proportion of cases. Some had developed their anaemia very suddenly and had not responded even to intravenous iron. There were no cases resembling tropical macrocytic anaemia. He felt that malnutrition played an important part, most of the cases coming from an infertile area where cattle could not be raised. In the discussion which followed, the question of mineral deficiencies in the soil was raised, but analysis had not demonstrated any particular deficiency or excess.

Preventable Blindness

The following morning a clinical demonstration was given by the staff of the surgical division of the hospital. Cases were shown by Mr. I. W. J. McAdam and Mr. H. J. Croot, and Mr. D. P. Burkitt demonstrated artificial legs in various stages of construction, made locally from plasticized asbestos sheet. The legs were very light, unaffected by moisture, ant-proof and fire-proof, and cost £1 each.

The problem of blindness in Uganda was the subject of a paper by Dr. A. J. BOASE, who discussed some of the commoner causes. There were no reliable statistics, some putting the incidence of blindness as high as 1% of the population (5,000,000). Corneal blindness from keratoconjunctivitis and from trachoma accounted for some 80% of the blind seen at Mulago Hospital; these cases were avoidable. Contrary to the general belief, senile cataract was much the same in incidence as elsewhere, but the common occurrence of symmetrical cataract in young adults, probably hormonal or metabolic (not diabetic),

called for elucidation, as did also a not uncommon primary optic atrophy assumed to be of viral origin. "Hetrazan" promised much in onchocercal disease of the eye: a cited case, blind from bilateral papillitis, with the aqueous of each eye teeming with microfilariae, had made a dramatic recovery. The possibilities of surgery were shown in the case of a man who had been blind from trachoma: bilateral tarsectomy followed by bilateral penetrating keratoplasty had removed all signs of trachoma and restored vision.

African Children

Dr. R. F. A. DEAN then described his observations on African children. At the outset of his work he had been struck by several details which suggested a lack of masculinity in the physique of the boys, particularly in those from the wealthier strata of African society. He found that the older schoolboys (16 to 22 years old) had very little facial or bodily hair, and an unexpected smoothness of outline; 6 out of 180 had gynecomastia. Investigations of a group of boys 6 to 15 years old confirmed the findings of an intersexual type of physique; measurement of hand bones showed development proceeding in advance of a U.S. standard (although height and weight were below U.S. standards) and bodily proportions that were more nearly feminine than masculine.

Examinations of younger children (6 months to 3 years old) showed that they were developing poorly. It was from this age group that the majority of cases of kwashiorkor were derived. There seemed no doubt that protein deficiencies in the diet were responsible for the onset of this disease, and high-protein diets had been used successfully at Mulago Hospital. Up to 125 g. milk protein had been given daily. In the serum of 45 relatively uncomplicated cases the treatment had brought about rises in the concentration of total protein, albumin and globulin, and in the levels of many enzymes. All this was consistent with the relief of protein deficiency. There had also been a big rise in serum cholesterol. Attempts at increasing the amount of dried skimmed milk in the diet had disclosed an unexpected intolerance of carbohydrate. This extended to lactose, sucrose, glucose, and maltose, and was a severe handicap in therapy. One of the principal items in the local diet was the cooked banana or plantain, which contained very little protein. When this was given alone to experimental animals they developed fatty livers and changes in the pancreas. The youngest animals seemed most affected. In some experiments methionine added to the banana diet had seemed to prevent the development of the fatty livers, but there might be other deficiencies. Success in treatment of kwashiorkor might have been due partly to methionine, and a further trial of this amino-acid was in progress.

Many children probably passed through a period in which they suffered from kwashiorkor in an unrecognized mild form. They might, however, sustain liver damage which did not completely clear up, and which might underlie the high incidence of various liver diseases known to afflict Africans. It seemed possible that biochemical changes due to the disease might be responsible for many unexplained differences between Africans and Europeans. An upset cholesterol metabolism might, for instance, lead to the abnormal production of steroid substances and therefore to the development of intersexual characteristics and to unusual response to "stress." It was emphasized that the connexions between the pathological states found in the various age groups were so far tenuous and theoretical, but the speaker believed that a single pathology, having its origins in dietary insufficiency in infancy, was an economical and acceptable hypothesis.

The meeting was closed by the president, who thanked the speakers. He hoped many would return to the next annual clinical conference. This was the second held by the Uganda Branch, and there was an average attendance of over 50 members at each session, and over 70 members and guests had been present at the dinner. The Uganda Branch had a widely scattered membership, although the largest body of members was in Kampala; the purpose of

the annual clinical conferences was to give the up-country members a chance to attend meetings, and the council of the Branch were gratified by the large number who had attended.

ADDENDUM

BY

Professor W. C. W. NIXON

For the first time in the history of Makerere Medical School external examiners from the United Kingdom took part in the examinations in the final-year subjects. Sir Heneage Ogilvie (Guy's Hospital) examined in surgery and anatomy, Dr. J. H. Sheldon (Wolverhampton) in medicine, and Professor W. C. W. Nixon (University College Hospital) in obstetrics and gynaecology. Professor Esther Killick (London School of Medicine for Women) travelled with the group and examined in physiology.

The Uganda Branch of the British Medical Association arranged to hold its annual general meeting after the examinations so that the above visitors could participate. The organizers of the meeting are to be congratulated on the choice of subjects and the number of members attending. Ample opportunity was given to the visitors from home to examine patients in the wards of Mulago Hospital. Mengo Hospital, founded in 1844 by the late Sir Albert Cook, was also visited. There we were pleased to meet Miss Margaret Basden, who is working temporarily at "Mengo," having recently retired from the staff of hospitals in London.

The visitors from Britain made new friends, exchanged ideas, and acquired fresh knowledge. By the meeting being held at Makerere College members were given the chance of seeing the way this medical school is developing and how it was achieving its aim to train Africans as doctors. Its staff is to be congratulated on the way it is handling this task and deserves all the support possible from colleagues at home.

There can be no doubt that the Uganda Branch of the B.M.A. is one of the most active and thriving overseas.

ORDER OF ST. JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:

As Knights: Major-General P. H. Mitchiner, C.B., C.B.E., T.D., Lieutenant-Colonel C. G. Booker, M.D., Major E. S. B. Hamilton, M.C., M.B., F.R.C.S., Captain R. V. Steele, M.B., Drs. K. S. Maurice-Smith, F. L. Newton, N. Manson, C.B.E., and F. L. Richard. *As Commanders (Brothers):* Sir William Coates, K.C.B., C.B.E., D.L., V.D., T.D., F.R.C.S., Surgeon Captain A. McCallum, O.B.E., M.D., Brigadiers W. H. du Plessis, O.B.E., M.R.C.S., L.R.C.P., and T. W. Davidson, M.B., Colonels C. H. S. Redmond, T.D., M.B., and O. L. Shearer, C.B.E., M.B., Lieutenant-Colonel G. G. L. Stening, M.B., Drs. J. T. Whitley, O.B.E., M. C. Lavin, K. E. Dowd, F. C. Middleton, M.B.E., C. R. de C. Sadler, and W. R. Russell, and Mr. F. W. Law, F.R.C.S. *As Officers (Brothers):* Major-General F. K. Norris, C.B.E., D.S.O., M.D., Lieutenant-Colonel F. K. Mugford, M.B., Captains G. R. H. Wrangham, M.R.C.S., L.R.C.P., and J. C. Mead, M.B., F.R.C.S., Drs. F. MacLagan, A. D. D. Broughton, M.P., E. M. Dearn, G. E. Sawdon, W. J. Griffiths, F. C. O'Mara, T.D., G. W. Gale, R. P. Myers, W. P. Warner, C.B.E., D.S.C., W. W. King-Brown, J. G. F. Hosken, R. W. Harte, D. A. Balgate, N. C. Speight, C.B.E., T. H. Pettit, E. C. Brewis, and E. A. Daley, Messrs. H. B. Stallard, M.B.E., M.D., F.R.C.S., S. L. A. Manuwa, O.B.E., M.D., F.R.C.S., and G. W. A. Keddy, M.D., F.R.C.S. *As Associate Officer (Brother):* Dr. J. Cohen. *As Serving Brothers:* Lieutenant-Colonel H. B. Porteous, M.B.E., M.D., Majors M. S. Harvey, M.B., S. Newsom, M.B., F.R.C.S., H. C. Stewart, M.D., M.R.C.P., and T. MacF. Wilks, M.B.E., T.D., M.R.C.S., L.R.C.P., Captain J. N. L. Thoseby, M.B., Drs. S. S. Datta, M. Y. Paget, A. Armit, E. E. Kath, J. Gregoire, J. Howie, F. F. P. Malcolm, F. A. Brown, G. E. J. Porter, W. E. Hadden, C. Wilson, A. Russell, J. A. Lees, O. H. D. Oliver, R. G. Eastwood, J. Walker, C. W. Walker, B. Reports of Societies

VITAMIN B₁₂

A conference on vitamin B₁₂ was held by the Nutrition Society on January 5 at the London School of Hygiene and Tropical Medicine. Professor L. J. WITTS, who presided, explained how knowledge of this recently discovered vitamin, which is remarkable for containing cobalt and for its potency in minute doses, had developed through two distinct channels. First, it had long been recognized that human pernicious anaemia could be cured by the administration of liver extracts. The active principle had been described by Castle as the "extrinsic" factor; in the absence of therapy it could not be absorbed in adequate amounts from the intestinal contents when the stomach wall failed to elaborate the "intrinsic" factor. Secondly, it had been noticed by workers interested in promoting rapid growth in farm animals, particularly poultry, that diets of entirely vegetable origin were unsatisfactory. The presence of an "animal protein factor" had been demonstrated, and its distribution studied in various foodstuffs of animal origin. Eventually it was realized that the human "anti-anaemic" factor could be identified with the "animal protein factor," and that the substance concerned could be classed as a water-soluble vitamin.

In spite of intense research our knowledge of vitamin B₁₂ was still incomplete, particularly about its chemistry, the mechanism by which its absorption is assisted by the unidentified "intrinsic" factor, and its method of action in the tissues. The important interrelationship with folic acid had attracted much attention: while folic acid could cause a temporary improvement in the blood picture in pernicious anaemia it could not replace vitamin B₁₂ in protecting the nervous system. Many other interrelationships, such as that involving folic acid, ascorbic acid, and tyrosine, required further investigation.

Isolation and Chemistry

Dr. E. LESTER SMITH described how vitamin B₁₂ was first isolated from liver extracts by processes depending mainly on adsorption on charcoal followed by elution and chromatography on alumina. The numerous intricate operations had been facilitated when it was realized that the vitamin was highly coloured, and that its position on the adsorption column could be clearly observed as a bright pink region. Before the importance of this clue was realized progress towards the isolation of the crystalline vitamin had been retarded by the absence of a suitable animal test, which meant that all fractions had to be tested directly upon patients with pernicious anaemia.

Vitamin B₁₂ was present in animal tissues, with liver and kidney as the richest sources, but absent from all plant tissues except small roots. It was synthesized by *Streptomyces griseus* and various other micro-organisms, and these had replaced liver as industrial sources. Presumably the accumulations of the vitamin in animal tissues were derived ultimately from micro-organisms.

Attempts to elucidate the chemical structure of vitamin B₁₂ by hydrolysis had indicated the presence of a cyclized form of ribose and a benzimidazole ring, and a small part of the molecule therefore appeared to resemble the vitamin riboflavin. The rest of the large molecule contained cobalt, a cyanide group, phosphoric acid, two 1-amino-2-propanol groups, and a large unresolved residue with the composition C₂H₅₅N₉O₄. Other active substances, differing slightly from vitamin B₁₂, had been detected in natural sources and prepared artificially. Numerous biological and microbiological tests were now available.

for antihistamine therapy in children

The Elixirs of 'Anthisan' and 'Phenergan' provide convenient means of administering Antihistaminics to children. Palatably flavoured and pleasant to take they facilitate graduated dosage.

'Anthisan' Elixir

trade mark brand
mepyramine maleate

which combines specific antihistamine activity with rapidity of action.

'Phenergan' Elixir

trade mark brand
promethazine hydrochloride

an antihistaminic with a prolonged action.

Dosage

Total **daily** dose to be given in **divided** administration.

'ANTHISAN'

Up to 1 yr.: 25-75 mgm.
(1 to 3 fluid drachms).

1 to 2 yrs.: 37.5-100 mgm.
(1½ to 4 fluid drachms).

2 to 3 yrs.: 50-125 mgm.
(2 to 5 fluid drachms).

3 to 4 yrs.: 75-200 mgm.
(3 to 8 fluid drachms).

4 to 7 yrs.: 100-250 mgm.
(4 to 10 fluid drachms).

7 to 14 yrs.: 150-400 mgm.
(6 to 16 fluid drachms).

'PHENERGAN'

Up to 2 yrs.: 10-20 mgm.
(2 to 4 fluid drachms).

2 to 5 yrs.: 15-25 mgm.
(3 to 5 fluid drachms).

5 to 10 yrs.: 25-50 mgm.
(5 to 10 fluid drachms).

Supplies

'ANTHISAN' ELIXIR Bottles of 4 and 40 fl. oz. (each drachm contains 0.025 Gm. mepyramine maleate).

'PHENERGAN' ELIXIR Bottles of 4 and 40 fl. oz. (each drachm contains 5 mgm. promethazine hydrochloride).

'DISTIVIT' B₁₂

brand

'Distivit' B₁₂ is a sterile aqueous solution of crystalline vitamin B₁₂, the most potent anti-anaemic substance known. Vitamin B₁₂ is highly effective in the treatment of Addisonian pernicious anaemia, including the neurological complications of the disease. Good responses in other types of macrocytic anaemia have been recorded. There are no known contra-indications to its use and there is no evidence that it gives rise to undesirable side-effects or to sensitization. 'Distivit' B₁₂ is issued in three strengths in ampoules containing 20, 50 and 100 micrograms per ml. in boxes of 5 x 1 ml. ampoules.

"SANOID" STERILISED SURGICAL CATGUT

Over forty years' experience is behind the manufacture of "Sanoid" Sterilised Surgical Catgut. Our capacity has recently been considerably increased to enable us to fulfil increased demand.

TENSILE STRENGTH: "Sanoid" Surgical Catgut easily surpasses official requirements for minimum average strength.

GAUGING: Every strand of "Sanoid" Surgical Catgut has been checked at four points by dial micrometer.

Prepared under M.O.H. Licence No. 40

FLEXIBILITY: Heat treatment necessarily tends to make catgut to some degree wiry and brittle due to loss of moisture, but the composition of the solution in which "Sanoid" Surgical Catgut is tubed is such that the maximum possible strength and flexibility are restored to the gut and retained by it under long storage periods.

SMOOTHNESS: "Sanoid" Surgical Catgut is of great smoothness, but at the same time holds securely on the knot.

STERILITY: "Sanoid" Surgical Catgut conforms to the stringent bacteriological tests for sterility as laid down by the Ministry of Health in the Therapeutic Substances Regulations.

We invite your inquiries for Catgut and other Surgical Ligatures. Samples will be provided with pleasure.

A PRODUCT OF **Cuxson Gerrard & Co. Ltd.** OLDBURY, BIRMINGHAM

Therapeutic Value

Dr. C. C. UNGLEY discussed the value of vitamin B₁₂ in the treatment of various forms of anaemia, and explained that it was only effective when the bone marrow was megaloblastic. Not all forms of megaloblastic anaemia, however, responded to therapy. Thus the anaemias of pregnancy and the puerperium, as observed in temperate climates, failed to respond to vitamin B₁₂ but were corrected by folic acid. The so-called "tropical sprue" sometimes responded to vitamin B₁₂. Anaemia associated with cirrhosis of the liver was seldom megaloblastic, but, when it was, vitamin B₁₂ might be effective. Anaemia after total gastrectomy had been corrected by folic acid, but not by vitamin B₁₂. Anaemia produced by a fish tapeworm had been cured either by vitamin B₁₂ or by the expulsion of the worm; the parasite had been found to be rich in vitamin B₁₂, and presumably caused anaemia by absorbing supplies otherwise available to its host.

Dr. Ungley emphasized that, while vitamin B₁₂ could correct not only the blood picture in pernicious anaemia but also the glossitis and nervous lesions, folic acid could only temporarily correct the blood picture. Doses of 1 µg. often produced definite improvement, but when patients had nervous lesions or suffered from intercurrent disease 100 µg. monthly should be allowed.

Dr. R. H. GIRDWOOD dealt with the complicated interrelationships between vitamin B₁₂, folic acid, and folinic acid both in the nutrition of micro-organisms and in the cure of anaemia. He concluded that both vitamin B₁₂ and folic acid were necessary for normoblastic blood, and that folic acid was probably converted in the body to folinic acid. Other factors, such as ascorbic acid and the anti-anaemic factor of Wills, were also important, and the picture might be further complicated by the presence of inhibitory factors.

Dr. J. E. FORD described microbiological methods for the estimation of vitamin B₁₂ based on the growth of *Euglena gracilis*, *Lactobacillus leichmannii*, and *Bact. coll.* and stressed the effect of the method chosen upon the comparative potencies of different sources of the vitamin.

Vitamin B₁₂ and Other Growth Stimulants

Dr. W. F. J. CUTHBERTSON gave an interesting account of the effect of supplements of vitamin B₁₂ and certain antibiotics in promoting growth, mainly with reference to poultry. Widely different results had been obtained in different laboratories according to the diet given and to the condition of the poultry house. Poor growth was usually obtained when an exclusively vegetable diet was given without supplements, and vitamin B₁₂ and other substances associated with it in its bacterial sources might then have dramatic effects in improving growth. When diets containing fish meal, however, or some other source of animal protein were supplemented by further supplies of vitamin B₁₂, or of an antibiotic such as "aureomycin," the findings of different workers might be very inconsistent. Thus with the same basal diet supplements of an antibiotic improved the growth of chicks in one locality but not in another. The cause of these disparities was presumably to be found in differences in the bacterial flora of the poultry houses. According to the nature of the bacteria they might either assist the chicks by synthesizing vitamin B₁₂ and yielding it up on digestion in the alimentary tract or merely compete with the chick by absorbing such supplies of vitamin as were available in the food.

Miss M. E. COATES supported this view. Of two poultry houses in the same institute, one was new, while the other had been used for several years. Chicks grew equally well in the new house with or without antibiotics, but in the old house supplements of antibiotics caused a considerable increase in the growth rate. The restriction of hens to a diet deficient in vitamin B₁₂ greatly reduced the hatchability of their eggs.

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Homes for Incurable Children

SIR,—The Invalid Children's Aid Association is occasionally confronted with a small but very urgent need affecting a special class of child. Every doctor and midwife will have had experience of cases of babies with meningoceles who are paralysed and incurable, of babies with hydrocephalus at birth, with multiple congenital deformities, absence of limbs, osteogenesis imperfecta, and other rarer conditions. These babies are sometimes so deformed and so difficult to manage that they need special care, which they may not be able to get in their own homes or in ordinary nurseries.

This association would never wish to encourage parents to evade their proper responsibilities for their children, whether normal or abnormal, and many babies of the kind mentioned can be, and are, dealt with in their own homes. Our social workers are sometimes able to help parents and to put them in touch with available community services. But humanity and common sense sometimes dictate that other arrangements must be made for these babies if home accommodation is unsuitable, if there are older children who are still needing a good deal of care from the mother, or if the parents by temperament and character are unable to face the anxiety and heavy responsibilities entailed. At present, parents, almoners, children's officers, and others are sometimes faced with an emergency which leads to a frantic search for accommodation, and often the resulting arrangement is wholly unsatisfactory and inflicts considerable hardship.

Our association knows that, legally, public authorities should provide accommodation for children of this kind, but all too often the bed for the long-term case is just not there. We now propose to start and maintain a register of hospitals, nursing-homes, and suitably qualified private persons who are prepared to take on an especially difficult baby. Particulars of accommodation offered should be sent to the General Secretary, I.C.A.A., 4, Palace Gate, London, W.8. The number of cases involved is small, so that even a short list of suitable homes would be a real blessing in desperate need.—We are, etc.,

A. WHITE FRANKLIN,
Chairman, Executive Committee.

LETTITIA FAIRFIELD,
Chairman, Homes Administration Committee.

Invalid Children's Aid Association,
London, W.8.

G. RATTENBURY,
General Secretary.

Death on the Roads

SIR,—During the last few years, acting as police surgeon, I have examined over 200 motor-car drivers arrested and brought to various police stations in the West End of London charged with being "under the influence."

Urine or blood tests are not usually employed. If the accused states that he has had no alcohol at all, a blood test for alcohol is asked for. In every case so far this request has been refused. Metropolitan magistrates have told me that they are not greatly impressed on being told that the blood contains a certain percentage of alcohol. They prefer to base their decision on the evidence of the police officers and surgeon. These magistrates have great experience, and they ought to know. The principal of a very well known London pathological laboratory tells me that these tests present certain technical difficulties, and that, as he is called upon only very seldom to perform them, he would prefer not to have that responsibility. If such tests are to be employed regularly it seems that it would be well to have each sample analysed at more than one laboratory.

The fate of the 200-odd cases examined may be of some interest. The following figures are approximate, but fairly accurate:

40% of them were dismissed by me. Half an hour or more elapses between the time of arrest and the time of examination. Arrest has a sobering effect. All these dismissed cases showed evidence of having had a considerable amount of alcohol, with the exception of three, all of whom were diabetics suffering from overdosage of insulin. This is the only condition I have come across which simulates drunkenness closely. Of the 60% certified by me about one-third plead guilty, of the remainder about one half elect to be tried by the magistrate; the others ask for trial by jury at the County of London sessions.

The magistrates find about 75% guilty. The court of sessions finds about 75% not guilty.

Even when the accused wins his case at sessions it is expensive; when he loses, it is very expensive, and the penalty is severe. Even so the gamble is well worth while. This 75% acquittal is a curious phenomenon. Cases which appear to be guilty beyond any possible doubt are frequently thrown out by the jury. It may be that the reason for this is to be found in the wording of the charge: "Being so much under the influence of alcohol as to be incapable of having proper control of a motor vehicle." Many cases are arrested as they are about to start their cars; others are able to show that they have in fact driven their cars some distance without mishap. In the first case there is no absolute proof that they were incapable; in the second it would seem that they were capable. Magistrates recognize the flaw in this sort of reasoning: juries apparently do not.

I have no legal training, and my opinion is of little value; but I believe that there would be more convictions and justice would be better served if the charge were amended to something like this: "Being in charge of a motor vehicle while so much under the influence of alcohol as to have one or more faculties noticeably deranged thereby."—I am, etc.,

London, W.9.

JAMES GOSSIP.

Anticoagulants in Leukaemia

SIR,—Sir Lionel Whitby in Part II of his Refresher Course on leukaemia (December 29, 1951, p. 1573) has painted a picture of this disease which is easy to see and understand, and for which I am grateful.

In the treatment of chronic leukaemia there is, I suggest, one omission. He does not mention the use of anticoagulants in those cases where the thrombotic manifestations are prominent. In two of the three cases of chronic leukaemia which have come under my care mesenteric thromboses occurred, in one case agonizing in the intensity of pain. These were completely relieved of thrombotic signs and symptoms by keeping the prothrombin level around 65% of normal by the use of dicoumarol.

Sir Lionel mentions the distressing symptom of priapism and the possibility of surgical treatment. One of my patients developed this symptom and was relieved by anticoagulant treatment. I thought these observations might be of use to others.—I am, etc.,

Leeds, 8.

R. A. MURRAY SCOTT.

Naevi in Pregnancy

SIR,—The letter of Mr. John Stallworthy (December 1, p. 1341) referring to the occasional appearance and growth of naevi associated with pregnancy prompts me to record a case I saw a few years ago.

The patient, a married woman with one child, noticed shortly after parturition the appearance of a small red papule in front of and just above the tragus of the right ear. There had been neither naevus nor telangiectasis on this site before or during pregnancy. The papule, which gradually increased in size, was itchy and bled when scratched. A few months later similar but smaller papules appeared on the tip of the helix of the same ear. Over the next two and a half years further lesions made their appearance while those that had appeared originally continued to increase in size. The new lesions were situated behind the right ear and on the skin of the face in front of the tragus.

There were no other naevi on her body, but she stated that at the age of 9 a red mark, unrelated to trauma, had appeared on the skin of her face in front of the right ear. This area, which was approximately $1\frac{1}{2}$ in. (3.7 cm.) long by $\frac{1}{4}$ in. (0.6 cm.) broad, was telangiectatic and was noticed at the time of the examination.

On examination it was seen that the tragus and upper part of the helix of the right ear had been replaced by tumour tissue, and there were two lesions on the skin of the face near the ear. A similar lesion was present over the mastoid area behind the ear. The growths were not large, had a port-wine colour, were firm but rather spongy in texture, and blanched on pressure. General examination revealed no abnormality and a blood picture was normal apart from a slight degree of hypochromic anaemia. The W.R. was negative. A biopsy report stated that the lesion was a simple tumour of either lymph or haemangiomatous type, or both, with a heavy chronic inflammatory type of perivascular exudate in which eosinophils were outstanding.

The patient was treated with x-ray therapy with considerable regression of the tumour, but because of my National Service duties I was unable to follow the case further.

Although there are few references in the literature to the spontaneous appearance or growth of naevi in association with pregnancy the condition has been described by Whitfield (*British Encyclopaedia of Medical Practice*, 1937, 5, 149) under the title "Progressive Angiomas of Pregnancy." He records a case of his own and quotes Gans as having figured a section of one from the cheek of a girl two months pregnant. Along the same lines Enticknap (*British Medical Journal*, 1946, 2, 51) recorded a fatal case of angioblastoma occurring in the breast of a woman three months pregnant, which he considered to have arisen from a pre-existing simple haemangioma.

I would like to thank my former chief, Dr. A. D. McLachlan, physician, Diseases of the Skin, Western Infirmary, Glasgow, for permission to record the above case.

—I am, etc.,

Glasgow.

W. O. THOMSON.

Cough Fracture in Late Pregnancy

SIR,—Dr. N. Wynn-Williams in his article on cough fracture (December 22, 1951, p. 1494) refers to a paper by myself and others on this condition in late pregnancy (*British Medical Journal*, 1949, 1, 135). We described four cases, and were able to find six others in the literature. The notable feature was that, in all, the left lower ribs were involved. It was our opinion that this fracture was relatively common in late pregnancy, and probably largely unrecognized. Dr. Wynn-Williams suggests that this fracture and pregnancy are a "fortuitous association" and not a clinical entity.

In the last two years I have seen four more examples in pregnant women, all left sided and affecting the lower ribs. No special effort was made to find them, other than a casual request to one or two of the assistants in the antenatal clinic to keep a look-out. Two were discovered in this way. The third came to light after I had overheard a conversation between a doctor and his wife about a patient requesting a visit. The fourth came to me because of chest pain of two years' duration.

I agree with Dr. Wynn-Williams that cough fracture unassociated with tuberculosis is common enough, and have seen six other such patients in the last four years; however, in these there is no such clear-cut tendency for the left side to be affected as there seems to be in our series. We discussed some of the possible causes of this left-sided predominance in our paper. The fact that all cases so far reported have occurred in the last three months of pregnancy cannot easily be dismissed as due to chance.—I am, etc.,

Ipswich.

J. W. PAULLEY.

Skin Resistance to Ultra-violet Light

SIR,—Dr. Klaus A. J. Järvinen, of Helsinki (December 8, 1951, p. 1377), has reported some interesting observations on the effect of systemic cortisone therapy on the reaction

of the skin to ultra-violet light. He has found that it doubles the minimal erythematous dose, and he also states that when the same patients were submitted to six minutes' exposure before, during, and after cortisone therapy the effect of cortisone was to promote pigmentation and, as one might therefore expect, to diminish the harmful erythematous and vesicular reaction.

From these simple and precise observations Dr. Järvinen draws the somewhat surprising conclusion that in this respect cortisone is not increasing the resistance of the skin to the injurious effect of ultra-violet light, but rather suppressing the normal protective mechanism by which this resistance is augmented and maintained. This can be true only if we regard erythema and vesiculation as a protective mechanism and pigmentation as an injurious effect. Since the opposite is a more prevalent teleological interpretation of the phenomena of photosensitivity, I would like to submit that his experiments indicate a true increase in the resistance of the skin to ultra-violet light as exemplified by the doubling of the minimal erythematous dose and that they also suggest a stimulation of the protective mechanism if we are entitled to regard pigmentation in this light.—I am, etc.,

Merek and Co., Ltd.,
Montreal.

J. H. LAURIE,
Medical Director.

Night Pain with Fractured Clavicle

SIR,—Within the last 10 weeks I have had two cases in children under 5 of fracture of the outer third of the clavicle. Clinically they have been misleading in that there is no deformity; there is practically no loss of function—the child has been able to dress and undress itself apparently without pain, including pushing the affected arm into a jersey, etc.; there is no apparent general disturbance. There has, however, been one feature common to both cases, and that is pain at night in bed. I suppose the anatomical structure maintains position while erect, but on lying down and turning over in bed pressure is brought on the fracture, or is it relaxation of muscles while asleep? Both cases were found on x-ray examination.

I wonder if any other people have found this pain-in-bed story connected with fracture of the outer third of the clavicle in young children.—I am, etc.,

Hadlow, Kent.

J. B. MARSHALL.

Treatment of Anthisan Poisoning

SIR,—Your report of a further two cases of "anthisan" poisoning in children (December 22, 1951, p. 1530) prompts me to take out of their context some of the results of an investigation into the cerebral effects of histamine. This investigation, which will be published eventually, necessitated the administration of anthisan in toxic doses to a large number of animals. The findings were so uniform in all the species examined (mouse, rat, guinea-pig, and rabbit) as to favour the view that they might also apply to human beings, especially as the clinical features of anthisan poisoning are very similar in man and animals.

Anthisan is a central convulsant—i.e., the convulsions seen in poisoning are not a secondary effect of interference with respiration, as is sometimes suggested, but depend on a direct action of the drug upon nervous centres. The average convulsive dose is very near the average lethal dose, and the gravest view must therefore be taken of any case presenting convulsions. Death is the result of respiratory depression, which occurs after the animal has passed through the convulsive stage. With slow absorption of the drug the central nervous system shows successively depression, excitement and increased reflex activity, tonic-clonic convulsions, coma, and respiratory depression. These stages correspond to the severity of the intoxication, and all four stages are therefore only seen with fatal or near fatal doses. Anthisan may be classified with atropine as a "deliriant narcotic," and their similarity of action is not fortuitous.

Orthodox anticonvulsant drug therapy is likely to prove disastrous in anthisan poisoning. The administration of ether, chloroform, soluble barbitone, or "nembutal" to experimental animals, while leading to a prompt cessation of the convulsions, greatly diminishes the survival rate by hastening and deepening the

stage of respiratory depression. It should be remembered that convulsions, unless of great severity and long duration, are not a life-threatening symptom in themselves. Their abolition is therefore not usually a legitimate therapeutic aim unless it is achieved by means which relieve rather than deepen the underlying intoxication of the central nervous system.

The effect of histamine on anthisan poisoning is markedly diphasic. In relatively small doses it has an important anticonvulsant and life-saving action, while in larger doses it increases mortality. With simultaneous administration the greatest life-saving effect is produced by an anthisan:histamine acid phosphate ratio (weight for weight) of 4:1 in the guinea-pig and 1:1 in the mouse, using average lethal doses of anthisan. To translate this finding into terms of human therapy is extremely difficult, not only because of species difference but also because poisoning in human cases is usually by mouth and the amount swallowed is rarely known. Moreover, animal experiments suggest that it is very difficult to dislodge anthisan from its central receptors, and histamine therapy becomes successively less effective as the interval between anthisan and histamine administration grows. In spite of this, a cautious trial of histamine in these desperate cases can be recommended, especially as absorption of anthisan is often still proceeding when they are first seen by a physician. If histamine is tried as an antidote, steps must be taken to protect the patient from the acute and severe hyperchlorhydria which will ensue.

Morphine occupies theoretically an ambivalent position in the treatment of anthisan poisoning. As a respiratory depressant it would seem to be contraindicated, as a histamine-releasing drug it might be an ideal therapeutic agent. Preliminary trials in mice have not yet given an unequivocal answer, but I think that a clinical trial of its efficacy as an antidote would be justifiable. Judging from animal experiments, it is certainly preferable as a sedative to barbiturates in these cases.

Adrenaline and atropine hasten death from anthisan poisoning in experimental animals.

On these imperfect data we may base the following scheme of treatment:

1. Wash out the stomach.
2. Treat the patient in a darkened room and avoid all unnecessary stimulation.
3. Do not administer inhalation anaesthetics or barbiturates.
4. If drug therapy seems desirable, try morphine or histamine, the latter in doses no greater than the amount (weight for weight of histamine acid phosphate) thought to have been absorbed by the patient.
5. Watch for respiratory depression, and give respiratory stimulants if it supervenes.
6. Take any supportive and eliminative measures which are not in conflict with the above.

An improved outlook in anthisan poisoning will result from the conscientious reporting of all cases with full notes on the treatment, even if unsuccessful. Meanwhile a certain number of lives may be saved by attention to these (largely negative) injunctions.

These observations probably apply to a greater or lesser extent to all antihistamine drugs. They are all central convulsants in toxic doses, and it is to be assumed that the mechanism of production of toxic manifestations is the same. I cannot conclude these remarks without making reference to the great help which I have received from Dr. Roy Maxwell, of May and Baker, Ltd., both in the supply of drugs and in the giving of expert advice.—I am, etc.,

Edinburgh.

ERICH GERINGER.

Discovery of the Formol Gel Reaction

SIR,—I am very much indebted indeed to Colonel W. C. Spackman for his letter (October 13, p. 911) about the discovery of the formol gel reaction, as it provides a very good opportunity for me to give a short account of the history of this discovery in the light of real facts, and not as presented in some publications.

In September, 1920, while I was a medical student and assistant at the Diagnostic Laboratory of Dr. Gaté, of the Bacteriological Institute of Lyons (France), there was a violent explosion that destroyed part of the Institute, including the refrigerator in which I used to keep the mixture of positive and the mixture of negative

serums of the previous week's Wassermann tests. Being at that time responsible for these tests and wondering where to keep the serum-controls each time used, I thought of adding to them a few drops of formol.

When I next wanted to use these serum-controls I observed that the positive mixture had jellified and was stuck to the bottom of the test-tube, while the negative mixture remained fluid, with no change whatsoever. This phenomenon seemed strange to me, and made me wonder whether, if repeated, it could not be used as a specific reaction for the diagnosis of syphilis. I tested immediately with formol some serum specimens, syphilitic or not, that I had available, and next day I observed that the former became jellified while the latter remained unchanged. I communicated this to Dr. Gaté, who during the succeeding days sent me from the Antiquaille Hospital of Venereal Diseases, in which he was assistant, a great number of syphilitic blood specimens for testing them comparatively with formol and at the same time by the Wassermann reaction.

The experiment was simple: To 1 ml. serum in an ordinary test-tube I added two drops of formol. Within 24-30 hours most of these sera jellified, and the results corresponded with Wassermann results in 85% of cases. The findings of this research were presented to the Société de Biologie at its meeting of November 15, 1920, and the relevant communication, entitled "Une nouvelle réaction des sérums syphilitiques: Formol-Gélification," appeared in the *Comptes rendus de la Société de Biologie*, 1920, 83, 1432.

The reaction being easy to carry out, there followed a great number of publications, from which, as well as from our own, it was proved that the formol gel test is not a specific syphilis reaction, but occurs in various diseases and is due to some abnormality of one or more constituents of the blood serum. The reaction was naturally tested both by us and many other research workers in connexion with various diseases. It was also tested, for the first time, in kala-azar by Colonel Spackman,¹ who observed that its occurrence in that disease was very quick, and that besides getting jellified the serum also became turbid. He therefore suggested that the formol gel reaction might also be strongly positive in trypanosomiasis.

A month later² it was reported that Napier "has discovered a test which promises to be of great value in the diagnosis of kala-azar . . ." and that "the test is a modification of that described by Gaté and Papacostas, who found that the serum of syphilitic patients becomes jellified in 24 to 30 hours when to 1 ml. clear serum two drops of commercial formalin solution are added. When this test is applied to the serum of kala-azar patients an immediate white opacity develops and the serum jellifies within half an hour."

There followed almost immediately³ a communication by Fox and Mackie, stating that they were studying the Gaté-Papacostas reaction in kala-azar from July 21, 1921, and reporting the results of their research.

The findings of Napier's study were published by him seven months later.⁴ In addition to kala-azar, he reports a number of cases of other diseases in which he tested the reaction. In his study he states that in carrying out the test he used the technique described by Gaté and Papacostas. Owing, however, to the quickness with which kala-azar patients' sera become jellified and turbid, he deemed it advisable to redesignate the formol gel test of Gaté and Papacostas as the "aldehyde test" or "Napier test,"⁵ and has since used this reference for the formol gel reaction in all his papers, as well as in his book *The Principles and Practice of Tropical Medicine* (1946).

Let us now see how far this redesignation of the reaction can be justified.

As is known, when speaking of any chemical reaction whatever we mean "the action set up by one substance on another" (*Concise Oxford Dictionary*). Therefore for any chemical reaction two things are necessary—the reagent and the substance on which it reacts. In the case of the formol gel reaction, the two interacting substances are formol and blood serum.

Both Spackman and Napier used the same reagent as we did—i.e., formol—and on the same substance—the serum. In addition, they used the same technique—namely, 1 ml. serum, two drops of formol, and the ordinary laboratory temperature. The test, therefore, used both by Spackman and Napier is exactly the same as we first described and is as now universally used. And if in some diseases the reaction somewhat varies in regard to time and turbidity, this, we believe, can by no means justify a special redesignation of the reaction in each particular case. Furthermore, according to Napier the two specific features of the formol gel reaction whereby he justifies its redesignation to "Napier test" are not encountered exclusively in kala-azar cases. Numerous writers have noted that the quickness of reaction and turbidity do not constitute a rule in kala-azar, nor do they represent exclusive characteristics of this disease. In this con-

nexion we would refer, among others, to the relevant study of Froilano de Mello and Baretto,⁶ who observed the same opalescence in sera of malaria patients, lepers, and dysenteric and syphilitic persons. Napier himself,⁷ in his first study, reports kala-azar cases in which solidification occurred without complete opacity. I also, having studied kala-azar reactions for years in Greece, observed a great number of cases where reaction developed many hours later, and in others there was no turbidity. I sometimes noted these phenomena in the same patient at different times.

We now know some more morbid conditions in which the formol gel test appears as in kala-azar. This especially applies to Kahler disease (multiple myeloma), which was thoroughly studied by Bing,⁸ E. Delbarre,⁹ and others. In that disease jellification of serum occurs within a few minutes, and is followed by an intensive turbidity. According to Delbarre, in the above disease formol gel reaction is a fundamental symptom. But neither Bing nor Delbarre ever thought of changing the name of the reaction.

In one of our later studies, in 1922,¹⁰ on the formol gel reaction in various diseases we drew the conclusion that "the reaction is not specific for syphilis, and that it seems to act as a control of unknown humoral changes, possibly caused by general chronic morbid conditions," and in another communication¹¹ we stated: "Like so many other humoral reactions or blood tests, such as eosinophilia, which no one claims to be specific for a certain disease, but the theoretical and practical diagnostic value of which in many diseases no one questions, the formol gel reaction—a new blood serum test—though not specific for one disease, maintains its value for many morbid conditions. . . ."

At present, from numerous researches made by various workers, it appears that the formol gel reaction is due to the disequilibrium of serum proteins and particularly to the reversal of the albumin-globulin ratio. According to many writers, this is due to an increase in the globulin fraction, but several others think that, for its occurrence, some other secondary, but necessary, unknown factors are required.

Regarding the use of formol gel reaction in surra (trypanosome disease of camels), to which Colonel Spackman refers in his letter, priority in its application pertains to the French Plantureux,¹² who published his relevant study eight months before Colonel Spackman's publication.¹³

I have thought it necessary to set forth the foregoing details in order to put an end, once for all, to the confusion appearing in some publications, especially English and American, about the history and origin of formol gel reaction.

I wish to thank Colonel Spackman again for the opportunity he offered me by his communication, as well as the Editor of the *British Medical Journal* for his courtesy in publishing this long letter.—I am, etc.,

School of Hygiene,
Athens.

Gastric Carcinoma and Acute Perforation

SIR.—I read with great interest the article on acute perforation of gastric carcinoma by Mr. J. L. Kennedy (December 22, 1951, p. 1489), and it recalled to my mind a case which I operated upon about two years ago which showed some unusual features.

On October 28 a man aged 41 was admitted with a very severe epigastric pain of three hours' duration. There was a five-year history of epigastric pain which came on about two hours after meals and showed periods of remissions and exacerbations. In the last month before admission the pain had become very severe, but it was still related to meals. His appetite was good except in the week previous to admission, when he had taken very little

NEW ADVANCE in sex hormone therapy

Mixogen is the new Organon preparation presenting the male and female hormones physiologically balanced in one tablet for the treatment of all signs and symptoms of declining sex hormone function in either sex. The synergistic combination of these B.P. substances confers *beneficial results greatly exceeding any obtainable with much larger doses of either of the components alone*, without the unwanted effects occasionally associated with one-sided sex hormone therapy. The sense of renewed mental and physical vitality is a notable feature of the treatment.

The tablets are **FREELY PRESCRIBABLE UNDER THE N.H.S.**

"MIXOGEN" contains 0.0044 mg. ethinylœstradiol B.P. and 3.6 mg. methyltestosterone B.P. in each tablet.

MIXOGEN

Male and Female Hormones in one tablet

In Perspex tubes of 25 tablets and in bottles of 100, 250 and 500.

solid food because he was afraid to eat. When he was admitted he had typical symptoms and signs of a perforation, and from the history it was reasonable to assume it to be a perforated duodenal ulcer.

At operation there was a perforation in the anterior wall of either the first part of the duodenum or of the pyloric antrum of the stomach. As there was so much oedema it was difficult to say with certainty the exact site of the perforation. The perforation was dealt with and the patient made a rapid recovery. On the 14th day he was transferred to a medical ward, as was the usual practice in that hospital.

A fractional test meal on November 29 showed a normal free acid curve, but a trace of blood was found during the second and third hour. A chest radiograph taken about the same time was normal. On December 9 a barium meal showed a suspicious persistent filling defect in the pyloric antrum. Three days afterwards a gastroscopie was passed, but for no obvious reason would not pass beyond the cardiac sphincter.

It was noted on December 16 that his appetite was very good, but on December 19 he developed a slight pyrexia which persisted. His general condition from now on began to deteriorate. His haemoglobin was found to be only 53%, but despite repeated blood transfusions there was little improvement in the anaemia. It was thought to be an aplastic type, possibly due to secondary growths in the bone marrow. Blood culture had been found to be negative. On December 20 a chest radiograph revealed an opacity in the left upper zone, and on January 6 early ascites was noted and this became worse in the next few days. His general condition deteriorated and he died on January 28—exactly three months after the operation.

At necropsy he was found to have a carcinoma of the pyloric antrum, with an unusual pattern of secondary growths in the lungs, left suprarenal, and in several ribs.

The interesting features about this case were the history, suggestive of a perforated duodenal ulcer; the fractional test meal—no achlorhydria; that his appetite was good, even up to six weeks after operation; and that the condition deteriorated so rapidly after operation that one would infer that secondaries were present at the time of the perforation, and a gastrectomy would not have prolonged life. This finding agrees well with the general poor ultimate prognosis in these cases.

—I am, etc.,

Swansea.

W. O. WILLIAMS.

POINTS FROM LETTERS

Inflation of Lungs During Bronchoscopy

Dr. R. A. C. HERRON (Zürich) writes: I was most interested to read the article by Dr. R. Bryce-Smith (December 22, 1951, p. 1517) on inflation of the lungs during bronchoscopy. I was also gratified that this method should receive the wide publicity it deserves, as I have been using it for three years and know the obvious advantages, especially in safety for the patient (*Anaesthesia*, 1950, 5, 40).

Invite Russian Doctors

Dr. JOHN PEMBERTON (Sheffield) writes: I would like to support Dr. R. L. Kitching's suggestion (December 1, 1951, p. 1331) that the British Medical Association should invite a group of Russian doctors to this country. In addition to leading to a valuable exchange of medical knowledge and experience, such a visit might contribute a little towards a better understanding between our two countries, especially if our Russian colleagues were willing to stay with us in our homes.

Tissue Reactions to Protein Sensitization

Dr. J. T. SHIRLAW (Wigan) writes: "The eosinophil cell is worthy of greater attention," says Professor J. R. Squire in his lecture (January 5, p. 1). So far, the following facts have been established: Allergy is accompanied by an eosinophilia; the administration of cortisone brings about an eosinopenia together with a dramatic improvement in allergic diseases; cortisone lessens cell growth activity. Surely these are points of great significance. I do not agree that the "eosinophil may be regarded as being concerned with 'mopping up' the products of tissue damage"; the eosinophil only appears on the scene when the mopping-up process has been finished by other leucocytes and should therefore be regarded more as a repair cell. . . .

Correction

In the paper on "Tuberculous Meningitis," by Dr. S. Russell Jamieson (January 12, p. 83), in Case 29 (p. 84, column 2) the dosage of vitamin B₁₂ employed was given as 10 mg. This was a thousand times too high, and should read 10 µg.

Obituary

H. S. RAPER, C.B.E., D.Sc., M.B., F.R.C.P., F.R.S.
The death of Professor H. S. Raper on December 12 was recorded in the *Journal* of December 22 (p. 1527). We are indebted to Professor A. Wormald for the following appreciation.

The passing of Henry Stanley Raper removes from the ranks of British biochemists one of its most distinguished and revered leaders. His approach to medicine was basically scientific, for he was a member of that small but remarkable group of chemists who qualified in Leeds in the early 1900's and subsequently branched out and helped to develop the new chemical offspring, biochemistry. This group included Dakin, Dudley, Hartley, Raistrick, and Raper, and all have made contributions which will for ever keep their own names, and indirectly the name of their chemistry mentor, the late Professor J. B. Cohen, permanently recorded in the annals of biochemistry.

Raper's main interest was undoubtedly in medical science, but he was above all a magnificent chemist. His whole approach to physiology and medicine was through chemistry and biochemistry, and, although for the greater part of his career he was professor of physiology at Leeds or Manchester or Dean of the Faculty of Medicine at Manchester, he never lost his keen interest in all branches of biochemistry. His ability to keep up to date, and indeed to anticipate many new developments, made him the ideal adviser-in-chief. Chemists, biochemists, physiologists, bacteriologists, pathologists, and clinicians came to him with their problems, and rarely, if ever, did they go away without at least one and usually several valuable constructive ideas.

His biochemical interests were wide. With Leathes he wrote an excellent classical monograph on fats, and during the 1914-18 war he made valuable contributions in the field of chemical warfare defence. He was one of the first in this country to use (in 1936) deuterium in the study of the absorption and metabolism of fats, and in recent years, in collaboration with Harper, he made important advances in our knowledge of the hormone pancreozymin. It is probable, however, that he will best be remembered in biochemistry for his classical work on tyrosinase, an oxidizing enzyme responsible for producing much of the dark-brown and black pigmentation of many animals. It is to Raper and his colleagues that we owe our knowledge of the precise chemical changes involved in the enzymic conversion of the amino-acid tyrosine into the red pigment haemochrome which is the precursor of melanin.

His happiest working hours were spent in his laboratory. "How delightful it is," he wrote to me early in January, 1945, "to be able to use one's hands and do a few experiments. But alas, term begins on Tuesday with its lectures, committees, interviews, and what not, so it will only be in odd hours that I can escape to the laboratory bench." Many biochemists will regret that with his almost unrivalled skill as a biochemist he was given so little opportunity to develop the work he loved, but we may be happy in the knowledge of the major contribution he made in the wider field of medical education and in the organization of medical research. His friends, and they were truly legion, will treasure the memory of "a verray parfit, gentil knyght," in stature and in deed.

R. FOSTER KENNEDY, M.D., F.R.S.ED.

Dr. Robert Foster Kennedy, professor of neurology at Cornell University Medical College, and formerly president of the American Neurological Society, died in New York on January 7, aged 67.

Robert Foster Kennedy was born in Belfast. His grandfather was Professor R. F. Dill, and one of his cousins was the late Field-Marshal Sir John Dill. He

studied medicine at Queen's University, Belfast, graduating in 1906. Shortly afterwards he came to London as resident medical officer at the National Hospital for Nervous Diseases, Queen Square. In 1910, the year he was elected a Fellow of the Royal Society of Edinburgh, he accepted a post in the New York Neurological Institute. From then his reputation grew steadily, not only as a neurologist, but as a scholar, wit, and outstandingly good orator.

During the first world war he served with the British and French Armies and made a special study of shell-shock. He was mentioned in dispatches and created a Chevalier of the Legion of Honour. He received many honours during the course of his distinguished career: last year Queen's University conferred on him the honorary degree of D.Sc.

Dr. Macdonald Critchley writes: Dr. Foster Kennedy was "in the house" at the National Hospital, Queen Square, at the same time as the late Kinnier Wilson. This apprenticeship brought him in touch with such masters as Bastian, Horsley, Ferrier, Gowers, and Hughlings Jackson. When Foster Kennedy elected to leave this country and settle in New York he took with him the tradition of clinical brilliance which, added to his own great powers, rapidly and surely achieved success.

It was not long before Foster Kennedy acquired a considerable consulting practice, as well as a reputation as a teacher and a clinician of outstanding merit. Slowly his distinction throughout North America increased, until in the last few years he found himself the leading exponent of medical organic neurology in the United States. His numerous contributions included the "Foster Kennedy syndrome" of subfrontal tumours and considerations upon aphasia, especially loss of artistic ability after local brain disease. He was interested in the difficult problem of the relationship between the loss of speech and the level of general intelligence. Latterly his attention was turned to the neurological complications of spinal anaesthesia and to the nervous manifestations of allergy.

But if Foster Kennedy's place as a neurologist is well assured, he will surely be best remembered as a generous, cultured, courteous, and kindly friend. His patients, pupils, and colleagues held him in such esteem as is rarely found nowadays. He kept in close touch with neurologists in Europe, and his friends in Great Britain and his native Ulster were very numerous indeed. Mr. St. John Ervine has recently dedicated his latest volume to Dr. and Mrs. Foster Kennedy.

It is a commonplace observation—though not often expressed openly—that doctors make the best diplomats: certainly Great Britain never had a better ambassador in the New World than Foster Kennedy.

For the last year or two Foster Kennedy had borne with supreme patience the vicissitudes of an insidious but fluctuating illness which ironically enough entailed alarming neurological manifestations. Throughout this illness the patient's charm and courage were inextinguishable. Neurologists throughout the world—and particularly in this country—will mourn the passing of a great colleague and a great man.

F. J. H. writes: American medicine has lost a unique and distinguished personality by the death of Dr. Foster Kennedy. More than 40 years of practice in the United States did nothing to change his essentially British characteristics. He loved the country of his birth and its way of life, and he loved the sea. To pass from the hectic din of New York into the quiet garden of his charming old-world house on the East River was an unforgettable experience. Here he loved to sit and talk in his soft and gentle voice; for he was an entrancing conversationalist and a truly cultured man. His nature was kind and lovable, but he could yet display the fire of the reformer and determination of the pioneer, fiercely attacking what he considered wrong

or specious. Foster Kennedy understood well the meaning of real friendship, and his passing is a deep personal loss to those who were privileged to know him.

DALLAS B. PHEMISTER, M.D., F.A.C.S., F.R.C.S. (Hon.)

We announce with regret the death of Professor Dallas B. Phemister, of Chicago. He was 69 years of age. We are indebted to Sir Harry Platt for the following appreciation:

Phemister graduated in medicine from the old Rush Medical College in 1904, and after holding a number of resident posts began to prepare himself for his chosen career in academic and practical surgery by a training in physiological research. To this end he came to England and worked for a time with Starling at University College. His ambition was early realized in his appointment, soon after the first world war, to the full-time chair of surgery in the University of Chicago, with charge of the surgical division of the new Billings Memorial Hospital. Phemister soon became a force in American surgery, and, by the example of his outstanding integrity and single-minded devotion to the pursuit of truth, he set a standard both for himself and for his pupils which was always a challenge to the notion of material success as the hallmark of surgical leadership. Although he remained to the end a general surgeon—whatever that term may convey—Phemister's chief interests lay in the field of orthopaedics—bone growth, bone grafting, the arrest of longitudinal growth in young bones, the healing of fractures, and tumours of bone. His notable contributions to these subjects were always founded on a combination of experimental and clinical observations. He was elected a member of the American Orthopaedic Association in 1923, and many of his earlier papers were read before meetings of this body. He also played an influential part in the affairs of the American College of Surgeons, both as Regent and as Chairman of the Committee on Postgraduate Training. In 1949 he occupied the distinguished office of President, and in his presidential address expounded the virtues of the American version of the full-time professorial system in university departments of surgery, whereby the professor and his senior staff were remunerated by a composite salary to cover the three activities of teaching and research, the treatment of public patients, and the treatment of private patients within the university hospital.

On first acquaintance Phemister gave the impression of austerity, but behind a quiet and dignified exterior was a man capable of warm friendships. He was also in the best sense a "good European," and he valued highly the distinctions which came to him outside his own country—the Honorary Fellowship of the Royal College of Surgeons of England (1947), and the Vice-Presidency of the International Society of Surgery at the Congress in Paris in September, 1951, during which he received the Legion of Honour. As Emeritus Professor of Surgery in the University of Chicago he had just begun to look forward to further years of fruitful surgical research. During the meeting in Paris, his many British and Continental friends perceived no signs of decline in his mental and physical vigour. His death following an operation for appendicitis has removed from the world of surgery a man with unique personal and intellectual qualities who still had a message to deliver.

HENRI HARTMANN, M.D., F.R.C.S. (Hon.)

Dr. Henri Hartmann, who was appointed professor of clinical surgery in the University of Paris in 1909, died in Paris on January 2, aged 91. We are indebted to Mr. V. Zachary Cope for the following appreciation.

Probably no French surgeon has been, in his day, better known or more widely respected than Henri Hartmann, who as long ago as 1913 was thought worthy to be elected an Honorary Fellow of the Royal College of Surgeons. Anatomists still describe the "pouch" which bears his name, and surgeons still, in selected cases, practise the operation he devised for some cases of carcinoma of the rectum.

Henri Hartmann was born in Paris in 1860. He was a successful medical student, and gained the Prix d'Argenteuil in 1887. He became successively hospital surgeon, *agréé*, and professor at the faculty of medicine, and in 1918 was elected a member of the Academy of Medicine, of which he became president in 1936. In 1929 he had the distinction of presiding at the meeting of the International Society of Surgery held in Warsaw. In 1932 his friends and pupils presented him with a jubilee book to celebrate his 50 years of professional life.

Hartmann succeeded in 1909 to the chair of surgery at the Hôtel Dieu, where he performed about a thousand operations yearly for 20 years or more. He kept personal notes of all his cases, and had a wealth of experience that he drew upon in his many published works. He was a general surgeon in the best sense of the word. He wrote on tumours of the breast and on the treatment of war wounds, but his main work was within the abdomen. He wrote books on the surgery of the stomach, of the biliary passages, and of cancer in general; he also published a good book on operative gynaecology which was translated into English, and was for several years editor of *Gynécologie et Obstétrique*. He was one of the founders of the French League against cancer, and for his public work and distinction he was made a Grand Officer of the Legion of Honour.

Hartmann's clinic in Paris drew men from all parts of the world, and English surgeons regarded him as a man of outstanding surgical worth. The present generation furnishes few, if any, examples of such all-round surgical proficiency. In spite of the great activity of his life he reached a ripe old age.

The death occurred at St. Andrews on December 29 of Dr. JOSHUA FERGUSON in his 82nd year. He was the son of the Rev. Dr. Fergus Ferguson, a leading minister in Glasgow in his day. From Glasgow High School Joshua Ferguson went on to Glasgow University. He was a brilliant scholar, being prosecutor in anatomy from 1892 to 1894, taking his M.B., C.M. degrees with honours in 1895, and winning the coveted Brunton Memorial Prize awarded to the most distinguished medical graduate of the year. This reputation remained with him in after-years, and many of his fellow graduates continued to speak of him as "The Master." After a period in the Glasgow Western Infirmary he came to Paisley as an assistant to another notable doctor, the late Dr. Donald Fraser, and later he started on his own account. He practised in the town for over 40 years and was soon recognized as the leading physician in Paisley and district. Among his appointments were those of visiting physician to the Royal Alexandra Infirmary and the Royal Victoria Eye Infirmary, medical adviser to the firm of J. & B. Coats Limited, physician to the Coats Sanatorium, and medical referee in Renfrewshire under the Workmen's Compensation Acts. He was a Fellow of the Royal Faculty of Physicians and Surgeons in Glasgow and for a term he was president of the Royal Medico-Chirurgical Society of Glasgow. Apart from the practice of medicine he had many other interests. A man of wide culture and learning, he had

studied and absorbed all that was best in Greek, Latin, and English literature. As evidence of the extent and quality of his interests he was a president of the Paisley Philosophical Institution and for a term president of the Scottish Photographic Salon. Dr. Ferguson was a brilliant public speaker, his speeches being models of perfect phrasing and brightened by flashes of wit. He was a devoted churchman and for many years an elder in Paisley Abbey. It is not possible in a short appreciation to give a true picture of his qualities. One of his younger colleagues spoke of him as the ablest and most versatile man he had known intimately. His many patients remember him above all as the perfect doctor: he had remained a student all his life and kept himself in touch with all modern developments in the practice and art of medicine, so that he could proffer all that was best for their benefit. He had a way of inspiring confidence both in young and old, and his presence at a bedside was in itself a comfort and a cure. Dr. Ferguson retired in 1939 to St. Andrews. He is survived by his widow, a sister of the late Viscount Horne, who was Chancellor of the Exchequer after the first world war.—T. H.

Dr. W. H. MILLER, formerly senior surgeon at Bedford General Hospital, died suddenly at home on December 31, 1951, aged 70. Born in Newcastle-upon-Tyne, the eldest of a large family, William Henry Miller went with his parents to Canada, from whence he returned in 1893. He was educated at the William Ellis School in London, and went on from there to Guy's Hospital, where he won the Durham and Hilton Exhibitions. He qualified in 1906, graduated M.B., B.S. with honours in 1907, and proceeded M.D. with first-class honours and gold medal in gynaecology in 1911, the same year in which he became a Fellow of the Royal College of Surgeons. After acting as house-surgeon at Guy's Hospital, he became surgical registrar at the Samaritan Hospital. He went into practice first in Enfield, and then joined the late Dr. Hartley in Bedford. In the 1914-18 war he served as a surgical specialist in the R.A.M.C. Returning to Bedford after the war, he took over Dr. Hartley's practice, and eventually became the head of a large partnership. Always interested in surgery, he was appointed assistant surgeon to the Bedford County Hospital in 1924, and in 1932 he succeeded Mr. W. G. Nash as senior surgeon and chairman of the medical staff committee. When the National Health Service came into being in 1948 he was appointed consultant, and continued to do surgical work at the hospital until March, 1951. During this time many changes took place in the work of the hospital, and it was largely due to his inspiration and untiring enthusiasm that the hospital was brought so thoroughly up to date before the Ministry took over. At first interested in gynaecology, he became later expert in gastric surgery, which he raised to a very high standard in Bedford. He was particularly keen on giving his registrars and house-men a really practical training, and many will be grateful to him for his help and encouragement. This, too, can be said for his partners in general practice, where again he led the way by a very high standard and example. He was a most valuable member of the Bedford Group Hospital Management Committee, on which he served from its inception till the time of his death. He acted, too, as medical adviser to the Bedfordshire Hospital Services Association, where his sound judgment was greatly prized. During the second world war he was chairman of the local medical war committee. His life was saddened by the loss of his eldest son in 1940. He leaves a widow, a son, and a daughter.

A colleague writes: It is sad to contemplate practice in Bedford without the help of our great friend Dr. W. H. Miller. He was a strong man, and many of us learned to rely on his judgment not only in medical matters but in other directions as well. His opinions were decided, and never indefinite: they were mellowed by a very real humanity. Many of his friends and patients were delighted by the twinkle in his eye and by his charm and friendliness.

He was a man who never spared himself, and he inspired others to work with him. One felt that he really cared for the welfare of those for whom and with whom he worked, and he would take endless trouble to promote their interest both by sound advice and by practical help. He was a great fighter for things he thought right, and we all admired him for it. I know I express the feelings of all his old colleagues, patients, and friends when I say that his sudden death leaves a sense of great personal loss and that he will be sadly missed by everyone who knew him in Bedford.

Medico-Legal

EXPLOSION DURING ANAESTHETIC

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

On October 23, 1951, Mrs. Bessie Freeman, aged 55, who had been admitted to the Royal National Throat, Nose, and Ear Hospital, London, on the previous day for radical mastoidectomy on the right side, was found fit for operation, and about an hour and a half before the scheduled time was given premedication with "omnopon" $\frac{1}{2}$ gr. (22 mg.) and scopolamine 1/150 gr. (0.43 mg.). This was followed by "flaxedil" and thiopentone, and oxygen was then administered in the anaesthetic room. The anaesthetist was controlling the valve of the oxygen cylinder on the anaesthetic trolley and giving her the oxygen through an insulated rubber breathing-bag and facepiece, when there was an explosion. It appeared to be in the face-piece where he was holding it on the patient's face. He was thrown to the floor, and there was a fire on the trolley.

The patient was brought out of the room and aided respiration was maintained and an intratracheal tube passed. Her eyelashes were singed, her eyelids were bruised, and her nose was bleeding. In the theatre some blood was removed from her nose and pharynx, and bruising of the palate and post-pharyngeal wall was noticeable, but there was no active bleeding. As her pulse was good, and as her general condition seemed to warrant it, the surgeon decided to perform the operation. One hour and ten minutes after the explosion the patient collapsed. The operation had proceeded normally until then and was nearly finished. In spite of continuous restorative procedure the patient died in the ward about an hour and ten minutes later.

At the inquest, held before the North London coroner, the explosion was ascribed to static electricity, possibly sparking from the breathing-bag, where it might be generated by the movement of the bag itself, or from the movement of the anaesthetic tube against the patient's blanket. The bag was burst in the explosion. The anaesthetist's shoes were satisfactory and within the limits prescribed by the Ministry of Health, but atmospheric conditions in the anaesthetic room had been very favourable for the generation of static electricity. There was, however, no conclusive evidence of the cause of the explosion.

At necropsy the pathologist, Dr. F. E. Camps, found bruising of both upper and lower eyelids. There was bruising of the gullet right down to the stomach, of the larynx, and at the back of the throat. The force of the explosion was such that the stomach had been over-distended and had burst into the abdominal cavity. There was bruising round the heart and of the intestines, and rupture of the spleen and of the right lobe of the liver. There were some areas of bruising in the lungs, but the main force of the explosion had gone into the stomach. He said that nothing could have been done to save the patient's life after the explosion, and an exploratory operation of the abdomen would only have hastened her death. In spite of the extent of her injuries she might well have shown no symptoms except for a drop in blood pressure, and before the operation she had been suffering from high blood pressure. The cause of death was shock and haemorrhage due to rupture of the spleen and stomach.

A verdict of accidental death was returned.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Mr. Oliver Louis Zangwill has been appointed Professor of Experimental Psychology in the University from October 1, in succession to Sir Frederic Bartlett, F.R.S. Mr. Zangwill was educated at King's College, Cambridge, graduating B.A. in 1935 and proceeding M.A. in 1939. He has been Senior Lecturer in General Psychology in the University of Oxford since 1948. During the war he was research psychologist to the Brain Injuries Unit at Edinburgh, under the direction of Professor Norman Dött and Sir David Henderson. In 1946 the University of Oxford conferred on him the degree of M.A. The Chair of Experimental Psychology was established in 1931, when Sir Frederic Bartlett became the first occupant. His work has been concerned principally with problems of perception and remembering, and later with the development of the experimental studies of human skill and the problem of work in old age. He was elected F.R.S. in 1932.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College, held on January 10, with Sir Cecil Wakeley, President, in the chair, Mr. Gilbert Causey, who at present is Lecturer in Anatomy and Supervisor of the Museum, University College, London, was appointed as Sir William Collins Professor of Human and Comparative Anatomy at the College.

The Council passed resolutions of condolence on the deaths of Professor Henri Hartmann and Professor D. B. Phemister, both Honorary Fellows of the College.

The following were elected to the Fellowship of the Faculty of Anaesthetists: Dr. S. N. Albert (Beirut), Dr. A. F. Alsop (Oxford), Dr. G. Cousineau (Montreal), Dr. Phyllis M. Edwards (London), Dr. A. C. Forrester (Glasgow), Dr. A. P. Gorham (Bristol), Dr. N. R. James (Melbourne), Dr. J. R. Ritchie (Dunedin).

Diplomas were awarded, jointly with the Royal College of Physicians of London, as follows:

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—C. E. Bagg, J. Cowie, E. T. Downham, R. E. Glennie, Mei-Chen Liu, B. M. Mandelbrote, R. H. Martlew, Marion E. F. Woollaston.

DIPLOMA IN LARYNGOLOGY AND OTOTOLOGY.—K. D. N. Agrawal, A. Aziz, R. H. Cowling, Than Dok, H. Forer, J. D. Glanville, Beatrice A. J. Gregory, D. F. N. Harrison, W. A. Hopkins, H. M. Jones, Z. A. Khan, P. J. McNicholas, D. V. Maytham, J. R. Page, A. B. N. Rao, M. S. M. Refai, J. Vella, A. L. Wells, G. T. Woods.

DIPLOMA IN MEDICAL RADIODIAGNOSIS.—A. K. Banerji, S. M. Bingurnah, V. H. Bowles, J. Brown, T. Crisp, H. Ferguson, A. M. H. Fisher, H. L. Francis, K. D. Hatfield, H. W. Holland, D. T. Irwin, H. Jacobs, J. B. Jameson, Sheila Kenny, N. A. Lewtas, G. B. Mohanty, P. K. Mookherjee, J. J. Q. Peiris, K. M. Pillai, P. Purcell, Margaret P. Sheridan, G. P. G. Sim, A. G. G. Toomey, D. Urquhart, G. H. Waddington, D. R. Wallace-Jones, J. M. Winn.

DIPLOMA IN MEDICAL RADIOTHERAPY.—Diana M. Brinkley, G. E. Catton, J. H. O. Chance, P. M. C. Corlette, T. J. Deeley, F. M. Hall, P. Haslam, G. A. Hendry, G. Jarratt, G. Lynch, Dorothy Pearson.

DIPLOMA IN ANAESTHETICS.—Janie U. Blacker, A. K. Bose, Margaret L. M. Bridges, Margaret W. Brown, I. S. Bruce, R. W. Buckley, Cicely I. Butterworth, R. G. Cole, J. G. Cranmer, Patricia R. Ford, Elizabeth M. France, I. C. A. D. P. Graham, Edith H. Grundy, Mary J. Hartley, H. B. Houldsworth, J. S. Inkster, M. Junod, P. D. Kelsall, P. Koenig, C. J. Levy, Pauline McArthur, J. Mamak, W. K. Pallister, Edith J. L. Pearce, D. J. Power, J. E. Riding, R. J. Rutherford, A. K. Sen Gupta, Frances Sorrell, Heather Stockdale, J. C. Sumption, G. C. Tandan, M. Tappura, Hildegard H. M. Weisz, Margaret M. Whitaker, P. B. Wolfers.

DIPLOMA IN INDUSTRIAL HEALTH.—H. D. Conway, J. J. du Plessis.

DIPLOMA IN PATHOLOGY.—C. A. K. Bird, N. L. Modi.

DIPLOMA IN OPHTHALMIC MEDICINE AND SURGERY.—D. K. de B. Macdonald.

DIPLOMA OF OPHTHALMOLOGY.—K. D. N. Agrawal.

The following hospitals were recognized under paragraph 23 of the Fellowship regulations: Queen Alexandra Hospital, Army, six house officers (all for 12 months). Queen's Park Hospital, Blackburn, house-surgeon and senior house officer (both for six

months). St. Luke's Hospital, Guildford, surgical registrar for one year, second house-surgeon for six months (additional recognition). Royal East Sussex Hospital, Hastings, two house-surgeons for six months. Buchanan Hospital, St. Leonards-on-Sea, one house-surgeon (urological) for six months. General Hospital, Merton, senior house-surgeon for six months. General Hospital, Middlesbrough, orthopaedic house officer (senior) for six months (additional recognition). Shotley Bridge Hospital, surgical registrar for one year; two house-surgeons for six months. Royal South Hants Hospital, Southampton, registrar and house-surgeon for ear, nose, and throat department (decennial revision). Kent and Sussex Hospital, Tunbridge Wells, confirmation of recognition of post of senior house officer (ear, nose, and throat) previously recognized as registrar.

Vital Statistics

Infectious Diseases During 1951

The incidence of infectious diseases during 1951 was in several ways unusual. Their fluctuations are illustrated in the graphs shown overleaf, where a comparison is made with the highest and lowest weekly figures for 1942-50.

The number of notifications of scarlet fever was the lowest for recent years, while whooping-cough and measles were at the highest level since these diseases were made notifiable. The notifications of whooping-cough exceeded 5,000 cases a week six times during the first quarter of the year. In two weeks during the first quarter over 30,000 cases of measles were notified.

The fall in the incidence of diphtheria was continued during the year. The smallest weekly total of diphtheria during 1951 was 19, compared with 31, 52, 100, and 138 for the minima of the four preceding years. Examination of the trend of diphtheria during the last quarter suggests that the downward trend is being checked and the disease will become stabilized around the present level.

The number of notifications of dysentery reached a very high level, the largest weekly total being 1,672 cases. From the information available it seems that Sonne dysentery accounts for about 95% of the total notifications.

Acute poliomyelitis was much below the level of the two preceding years, but the incidence remains at 3 to 5 times the endemic level before 1947.

The enteric fevers (typhoid and paratyphoid) were more prevalent than in recent years, but the notifications were only about one-third of those during the outbreaks of 1941. The number of deaths from influenza in the great towns was the largest since 1937. The sudden rise in the curve for notifications of puerperal pyrexia and puerperal fever is due to the introduction on August 1, 1951, of a new definition of the disease.

A small feature of the graphs is that, with the exception of those for measles and influenza, they all show a decline in the number of notifications in the last week of the year, which includes the Christmas holiday, from the figure for the previous week; those for measles and influenza show only very small rises.

The number of notifications from the principal epidemic diseases for the past five years is:

England and Wales	1947	1948	1949	1950	1951
Scarlet fever	60,524	75,460	71,753	66,852	49,431
Whooping-cough	94,241	145,878	102,516	157,714	169,394
Diphtheria	10,528	7,903	4,929	2,858	1,969
Measles	399,461	396,841	384,761	366,116	615,332
Acute pneumonia	34,348	31,096	34,624	30,714	43,181
Meningococcal infections	3,147	1,971	1,586	1,745	1,956
Acute poliomyelitis	9,251	2,175	6,850	8,699	3,093
Dysentery	4,179	5,587	4,819	18,135	29,488
Enteric (typhoid and paratyphoid) fevers	880	873	1,138	654	1,438
Great Towns Influenza deaths	1,774	610	3,091	1,859	7,555

Record Low Infant Mortality Rate

Provisional figures published in the Registrar-General's *Quarterly Return* for the September quarter, 1951, show that the infant mortality and the stillbirth rates are the lowest ever recorded in England and Wales. Deaths of children under 1 year of age numbered 3,998, giving a rate of 23.5 per 1,000 related live births. The previous lowest rate recorded was 24.2 in the same period of last year. Stillbirths registered during the quarter numbered 3,727, giving a rate of 21.7 per 1,000 live and still births, compared with 22.5 in the September quarter of 1950. The previous lowest rate was 22.0 in the September quarter of 1949.

There were 168,028 live births registered during the quarter—a rate of 15.2 per 1,000 population. This is the lowest rate for a September quarter since 1941, when it was 14.0, and continues the decline recorded since the post-war peak of 20.0 in 1947.

Deaths at all ages registered during the quarter numbered 100,090, a rate of 9.1 per 1,000 population. This rate is average for the same quarter over the last five years. The births exceeded the deaths by 67,938. The corresponding increase for the same period of the preceding year was 67,220.

Week Ending January 5

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,102, whooping-cough 2,154, diphtheria 45, measles 3,491, acute pneumonia 973, acute poliomyelitis 25, dysentery 295, paratyphoid fever 6, and typhoid fever 2.

Infectious Diseases

In England and Wales during the week ending December 29, 1951, the incidence of infectious diseases decreased. The largest falls in the number of notifications were scarlet fever 457, whooping-cough 417, and dysentery 129.

A fall in the incidence of scarlet fever occurred in every region of the country; the largest declines were Lancashire 46 and London 40. Whooping-cough declined more in the northern section of the country than in the southern. The largest falls were Warwickshire 78 and Yorkshire West Riding 77.

The notifications of diphtheria were 11 fewer than in the preceding week. The chief variations in the local returns were an increase of 4 in Lincolnshire and in Lancashire, and a decrease of 8 in Staffordshire. The largest returns of diphtheria for administrative areas were Grimsby C.B. 5 and Liverpool C.B. 4.

The notifications of measles were 10 more than in the preceding week; the largest of the local variations were a rise of 57 in Staffordshire and a fall of 99 in Cardigan-shire.

The number of notifications of acute poliomyelitis was 5 fewer for paralytic and 3 fewer for non-paralytic cases than in the preceding week. The largest returns were Kent 3 and Cheshire 3.

A further 61 cases of dysentery were notified from the outbreak in Norfolk, Norwich C.B. The other large returns were Middlesex 37; Yorkshire West Riding 19; London 17; Bedfordshire 13 (Luton M.B. 12); Leicestershire 13 (Leicester C.B. 10).

Two large centres of food-poisoning occurred during the week. Buckinghamshire, Wolverton U.D. 133, and Northamptonshire 177 (Towcester R.D. 73, Northampton C.B. 52).

In Scotland a further 38 cases of dysentery were notified in Lanark county, where 101 cases occurred in the preceding week. The other large return in Scotland was 28 notifications in the city of Glasgow.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases (deaths from influenza) of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1942-50 are shown thus -----, the figures for 1951 thus ————. Except for the curves showing notifications in 1951, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

**INFECTIOUS DISEASES AND VITAL STATISTICS**

Summary for British Isles for week ending December 29 (No. 52) and corresponding week 1950.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 126 great towns in England and Wales (London included), London administrative county, the 16 principal towns in Scotland, the 10 principal towns in Northern Ireland, and the 13 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health, and Local Government of N. Ireland, and the Department of Health of Eire.

CASES In Countries and London	1951					1950

Medical News

Dinner for Lord Horder.—On Monday, January 7, a dinner was given in honour of Lord Horder's 81st birthday by his ex-house-physicians, at the Royal Automobile Club, Pall Mall. Dr. A. F. S. Sladden, as senior house-physician, was in the chair, and the toast of "our teacher," chosen because Lord Horder dedicated his medical notes to his teacher, Samuel Gee, was proposed by Dr. C. A. Hinds Howell, and supported by Sir Hugh Griffiths.

Travelling Fellowships in Ophthalmology and Otolaryngology, 1952-3.—The Medical Research Council invite applications for travelling fellowships in ophthalmology and otology for the academic year 1952-3, for which special provision has been made by the Alexander Pigott Wernher Memorial Trustees. Under the terms of the bequest from which these awards are made, the funds are to be applied "towards the prevention and cure of blindness and deafness in the United Kingdom and British Empire and in particular research in connexion therewith by financing medical men and students within the Empire to study methods and practices in all countries of the world." These fellowships are intended for suitably qualified medical graduates who are likely to profit by a period of work in ophthalmology or otology at a centre abroad before taking up positions for higher teaching and research in these branches of medical science. Candidates will be required to submit an outline of their proposals for study or research and to indicate their preference about place of work. The awards will, as a rule, be tenable for one year. The fellowships provide for the payment of stipend, together with an allowance for travelling and incidental expenses. The stipend will ordinarily be at the rate of £650 per annum for a single fellow, and of £900 per annum for a married fellow, subject to appropriate adjustment in the case of fellowships tenable at centres outside the sterling area. Forms of application for these fellowships may be obtained from the Secretary, Medical Research Council, 38, Old Queen Street, London, S.W.1, with whom applications must be lodged by March 31.

Hospital Renamed.—On January 1 the Sheffield Street Hospital, Kingsway, London, W.C.2, became part of the group of teaching hospitals known as St. Peter's and St. Paul's. To mark the change-over the hospital has been renamed St. Philip's. St. Philip's, which has 57 beds, will treat chronic urological cases.

Experimental Parasitology.—The first number of *Experimental Parasitology* appeared recently. This new quarterly journal intends to publish original contributions on experimental physiological, metabolic, biochemical, nutritional, and chemotherapeutic problems of parasites and host-parasite relationships. In addition, a section of the journal will be devoted to reviews covering all aspects of parasitology. *Experimental Parasitology* is published by the Academic Press, Inc., New York, at an annual subscription of \$8.00.

American Orthoptic Journal.—The American Academy of Ophthalmology and Otolaryngology has commenced publication of the *American Orthoptic Journal*, which will be issued as an annual supplement to the Academy's *Transactions*, and will contain papers read at its annual meetings.

Emergency Bed Service: Applications and Admissions.—During the seven days ending January 14 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,188, of whom 83.16% were admitted.

Wills.—Dr. William Arnott left £24,000. Bequests included £25 each to the West Riding Medical Charitable Society and the Royal Medical Benevolent Fund. Dr. Frank Constable Porter left £76,398, of which he gave £100 to the Benevolent Fund of the British Dental Association.

COMING EVENTS

Renal Association.—The eighth general meeting of the association will be held at the Ciba Foundation on Wednesday, January 30, at 4.30 p.m. Following the election to honorary membership of Dr. Donald van Slyke and Professor Dérot, papers will be read on the disorders of cellular hydration and experimental pyelonephritis, and Professor Dérot will describe 100 cases of anuria personally treated.

Memorial Service for Lord Addison.—A memorial service for the late Viscount Addison will be held in Westminster Abbey on Wednesday, January 30, at 12.30 p.m. No tickets will be needed by the general public, but seats will be reserved for relatives, Parliamentary colleagues, the Diplomatic Corps, and representatives of public bodies. Inquiries regarding arrangements should be made to Mr. Carol Johnson, Parliamentary Labour Party, Palace of Westminster, London, S.W.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Friday

UNIVERSITY COLLEGE, LONDON: FACULTY OF MEDICAL SCIENCES.—At Anatomy Theatre, Gower Street, London, W.C., January 18, 4.30 p.m., "The Hypothalamus and the Neuro-hypophysis," public lecture by Professor W. Bargmann (Kiel University).

Monday

ROYAL EYE HOSPITAL, St. George's Circus, Southwark, London, S.E.—January 21, 5 p.m., "Refraction Work in the Aged. Prescription and Fitting of Glasses," by Dr. T. H. Whittington.

Tuesday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 22, 5.30 p.m., "Involuntary Nervous System," by Professor G. L. Brown, F.R.S.

EUGENICS SOCIETY.—At Royal Society, Burlington House, Piccadilly, London, W., January 22, 5.30 p.m., "Recording Human Constitution," by Dr. R. W. Parnell.

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 22, 5.30 p.m., "Hysteria Cutis," by Dr. W. J. O'Donovan.

LONDON COUNTY MEDICAL SOCIETY.—At Talbot Restaurant, London Wall, E.C., January 22, 7 for 7.30 p.m., annual general meeting and dinner.

ST. ANDREW'S UNIVERSITY.—At Physics Lecture Theatre, Materia Medica Department, Medical School, Small's Wynd, Dundee, January 22, 5 p.m., "Some Recent Developments in the Study of the Biological Actions of Ionizing Radiations," by Dr. L. H. Gray, Ph.D.

Wednesday

●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 23, 5.30 p.m., "Mycology—Moniliasis: Torulosis," by Dr. R. W. Riddell.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., January 23, 4.30 for 5 p.m., "Tuberculosis of the Renal Tract," by Mr. F. R. Kilpatrick.

NORTH-EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At London Chest Hospital, Victoria Park, E., January 23, 3 p.m., "Congenital Abnormalities of the Chest," by Mr. T. Holmes Sellors. Pathological demonstration by Dr. K. F. W. Hinson.

SOCIETY OF CHEMICAL INDUSTRY.—At Burlington House, Piccadilly, London, W., January 23, 6.30 p.m., joint meeting of Nutrition Panel—Food Group and Oils and Fats Group. "The Digestibility of Fat," by Dr. H. Wilkinson, Ph.D., F.R.I.C.

Thursday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 24, 5.30 p.m., "Involuntary Nervous System," by Professor G. L. Brown, F.R.S.

●INSTITUTE OF CHILD HEALTH, Hospital for Sick Children, Great Ormond Street, London, W.C.—January 24, 5 p.m., "Surgery of the Brain in Childhood," by Professor H. Cairns.

LIVERPOOL MEDICAL INSTITUTION, 114, Mount Pleasant, Liverpool.—January 24, 8 p.m., pathological meeting.

MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, W., January 24, 8.15 p.m., "Testamentary Capacity," by Mr. W. Lacey, K.C.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—January 24, 4.30 p.m., lecture demonstration in neurology.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY, Lisle Street, Leicester Square, London, W.C.—January 24, 4.15 p.m., demonstration and discussion of clinical cases.

Friday

- CAMBRIDGE MEDICAL SOCIETY.—January 25, "Newer Developments in Radiotherapy," by Professor J. S. Mitchell.
- EDINBURGH UNIVERSITY: FACULTY OF MEDICINE.—At Anatomy Lecture Theatre, University New Buildings, Teviot Place, Edinburgh, January 25, 5 p.m., "Serum Cholesterol, 'Giant Molecules,' and Atherosclerosis," Macarthur Postgraduate Lecture by Professor Ancel Keys, M.A., Ph.D. (University of Minnesota).
- INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 25, 5.30 p.m., "Xanthoma and Necrobiosis Lipoidica," by Dr. P. D. Samman. Clinical demonstration.
- INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 25, 5.30 p.m., "Anaesthesia for Cardiac Surgery," by Dr. B. G. B. Lucas.
- MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, London, W.—January 25, 7.30 p.m., general meeting "Possible Applications of A.C.T.H. and Cortisone in Syphilis," discussion to be opened by Dr. Gordon Horne.
- OXFORD UNIVERSITY.—At Magdalen College, Oxford, January 25, 5 p.m., "The Neurophysiological Basis of Mind," Waynflete Lecture by Professor J. C. Eccles, F.R.S.
- ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—January 25, 8 p.m., "Human Faces," by Mr. A. R. Isaac.
- ROYAL SANITARY INSTITUTE.—At Public Hall, Lune Street, Preston, January 25, 10 a.m., papers: "Tuberculosis Control, with Some Comments on Lung Cancer," by Dr. W. Griffel; "The Changing Role of the Health Visitor," by Miss E. W. Sowerby, S.R.N., S.C.M.; "The Influence of Lighting Developments on Health and Safety," by Dr. J. N. Aldington, Ph.D.; 2 p.m., visits will be made.

Saturday

- SOCIETY OF PUBLIC ANALYSTS: NORTH OF ENGLAND SECTION.—At Engineers' Club, Albert Square, Manchester, January 26, 2 p.m., 27th annual general meeting. An ordinary meeting will follow. "The Use of Laboratory Animals as Analytical Reagents," by Mr. A. L. Bacharach, M.A., F.R.I.C.

APPOINTMENTS

- BRANNEN, IAN CAMERON, M.B., Ch.B., Registrar, Royal Northern Infirmary, Liverpool.
- HOSPITAL FOR SICK CHILDREN, Great Ormond Street, London, W.C.—Senior Surgical Registrar (Senior Registrar Grade), Ambrose Jolleys, M.B., Ch.B., F.R.C.S. Resident Anaesthetic Registrar (Registrar Grade), W. A. D. Combo, M.R.C.S., L.R.C.P. Assistant Resident Medical Officer (Senior House Officer Grade) at Tadworth, Elizabeth M. C. Dyke, B.M., B.Ch., D.C.H. House-physicians (Senior House Officer Grade), Kenneth Simpson, M.B., B.S., M.R.C.P., and M. J. Simpkins, M.B., Ch.B., M.R.C.P., House-surgeon (Senior House Officer Grade), M. R. Kliman, M.D., F.R.C.S.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

- Beynon.—On November 28, 1951, at Hong Kong, to Dr. Peggy Beynon (formerly Thomas), wife of Major Glanley Beynon, S.C.F., a daughter.
- Hatcher.—On November 13, 1951, to Joan (formerly Tanner), M.B., B.S., wife of Mr. Edmund Hatcher, a daughter—Susan Elizabeth Jane.
- Judson.—On January 4, 1952, at Hull, to Helen (formerly Atwell), wife of Dr. David Judson, a daughter.
- Kelsall.—On January 6, 1952, in London, to Margaret (formerly Miller), wife of Dr. A. R. Kelsall, a daughter.

MARRIAGES

- Slattery—Kelly.—On January 10, 1952, at St. Saviour's Church, Totland, Isle of Wight, John Anthony Slattery, M.B., B.S., of Canonbury, London, N., to Zoë Taschereau Kelly, M.B., B.S., D.C.H., of Freshwater, Isle of Wight.

DEATHS

- Carell.—On December 9, 1951, at South Elmwell, Yorks, Diana Pamela Mary Sylvester Carell, L.R.C.P. & S Ed., L.R.F.P.S.
- Clark.—On January 5, 1952, at The Vinery, Wellington, Hereford, Henry Colbatch Clark, M.R.C.S., L.R.C.P.
- Cockburn.—On January 12, 1952, at Southcliffe, Chalfont St. Peter, Bucks, Robert Pittar Cockburn, M.D., aged 86.
- Dobson.—On January 9, 1952, at Crawlands Hydro Hotel, Ilkley, Yorks, Maurice Rowland Dobson, O.B.E., M.B., B.S., aged 73.
- Dodson.—On January 2, 1952, Eleanor Isabel Dodson, M.D., of London, S.E., formerly of Multan, India.
- Greene.—On January 7, 1952, in a nursing-home, Jersey George Waters Greene, M.D., D.P.M., aged 74.
- Gregory.—On January 12, 1952, in London, Hazel Haward Chodak Gregory (formerly Cuthbert), M.D., F.R.C.P.
- Greig.—On January 6, 1952, at 23, Townsend Place, Kirkcaldy, John Isdale Greig, M.B.E., M.B., Ch.B.
- Grunhut.—On January 10, 1952, Jozef Grunhut, M.D., aged 51.
- Maddock.—On January 6, 1952, Edward Cecil Gordon Maddock, C.I.E., M.D., F.R.C.S. Ed., D.P.H. D.T.M. (Lieutenant-Colonel, I.M.S.), retired, of Wardon Lodge, Sunningdale, Berks.
- Molser.—On January 6, 1952, at 15, Watercall Avenue, Coventry, Lionel Henry Molser, M.B.
- Nicklin.—On January 8, 1952, at Luanshya, Northern Rhodesia, Reginald Nicklin, M.B., Ch.B.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Stains on Doctors' Clothes

Q.—What is the best way of removing stains on clothes due to (a) flavine, (b) iodine, and (c) blood?

A.—**Flavine Stains.**—Treat the stain with dilute hydrochloric acid or with dilute sulphurous acid, and then wash.

Iodine Stains.—These can readily be removed by sponging with a solution of sodium thiosulphate (photographic hypo). Dilute ammonia can also be used.

Blood Stains.—Fresh stains may be removed by sponging with cold or slightly warm (not hot) water, followed, if necessary, by the application of solution of hydrogen peroxide. The following methods are suggested in *Pharmaceutical Formulas*, published by the *Chemist & Druggist*—"In the case of delicate materials the following procedure is often successful: Prepare a paste of rice starch and water which is applied to the stain and allowed to dry on. Other methods consist in the application of a solution of borax, dilute solution of ammonia, tincture of quillaia, soap spirit, or solution of hydrogen peroxide followed by dilute solution of ammonia. A solution of tribasic sodium phosphate is also recommended for removing blood stains, and in some instances glacial acetic acid may be successful. In the case of old stains, these should first be thoroughly moistened with warm water, preferably with a slight addition of glycerin. In these cases the stains often yield to treatment with a concentrated solution of chloral hydrate (75%), after moistening the stain with dilute acetic acid. In recalcitrant cases of old blood stains a solution of pepsin, 4 gr. (0.25 g.); dilute hydrochloric acid, 20 min. (1.2 ml.); distilled water, 3 oz. (85 ml.) may prove successful in removing the albumin, followed by the application of one of the above-mentioned agents to remove the discoloration."

Hypnosis and Asthma

Q.—Is there any evidence that hypnotic treatment can benefit sufferers from chronic asthma? What might be its dangers, particularly with children?

A.—There is no doubt that very small factors, some of them psychological, can precipitate or inhibit attacks in a chronic asthmatic. At the end of a period of frequent attacks the patient may have acquired a faulty respiratory rhythm and posture which, through fear of future attacks, do not return at once to normal in a negative phase. At this stage, in children, education in relaxation of the respiratory muscles and in expansion of the bases can be aided by a method of suggestion such as hypnosis, which may for the time being eliminate this fear. This use of hypnosis is comparable with its use in stammering, where enduring improvement can be expected only if the child learns to relax apart from the hypnotic session. Even where a pre-existing asthma is used by the child as a purposive "functional" dyspnoea, a dramatic result should not prevent a search for causes of the underlying maladjustment, allergic, infective, or psychological.

A successful frontal attack on the asthma by means of hypnosis has often been reported, but usually where attacks are occasional. Many chronic asthmatics will report improvement because they cannot always tell the difference between an actual attack and wheeziness. They can easily be induced to feel that no attack is present and that none is pending.

The risks are those of any hypnotic treatment in children: that unless the children are carefully handled they may

develop a habit of going into unnecessarily deep hypnosis and of having anaesthesia, disturbance of memory, or tetany which may continue in the waking state.

Scrotal Retention Cysts

Q.—A male infant of 7 months has three or four white spots in the skin of the median raphe of the penis at its junction with the scrotum. The spots are about 2 mm. in diameter and are just under the cuticle; they appear to cause some irritation. What are they? What treatment is advised?

A.—It would appear from the description given that these spots are small retention cysts similar to the "epithelial pearls" or "Bohn's nodules" seen in the midline of the hard palate in most newborn infants and due to overgrowth of the epidermis covering over the mouths of the glands. The spots will disappear spontaneously. No treatment is necessary except regular cleansing of the parts.

Salt and Boils

Q.—Could an excessive intake of salt have any bearing on the development of recurrent axillary boils? A patient with this complaint takes a good deal of salt with his food, and also during his work. His job is to service water softeners and recharge them with salt; during the process he has to taste for brine until it is no longer noticeable in the water.

A.—There is no evidence that an excessive intake of salt could have any bearing upon the development of recurrent axillary boils.

Enuresis

Q.—Where can I find information on the investigation and treatment of enuresis?

A.—On p. 185 of the book "Any Questions?" The book can be obtained for 7s. 6d. (postage 6d.) from the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1.

Hazards of Ethyl Acetate and Toluene

Q.—Until recently ethyl acetate has been the solvent for lacquers in a factory where I am the doctor. Now 10% toluene is being added to the ethyl acetate to diminish the risk of fire, and there is a likelihood that the concentration of toluene in the solvent will soon be raised to 40%. Until the toluene was added, there had been no complaints of skin irritation from those handling either the solvent or the lacquer; now the men are complaining of burning and irritation when their hands and arms are exposed to the ethyl acetate-toluene mixture. (1) What are the known occupational hazards from ethyl acetate and toluene? (2) What can be done to reduce any such hazard? Are barrier creams, for instance, effective?

A.—(1) Ethyl acetate is an irritant and is mildly narcotic. In acute poisoning the irritant effects—e.g., acute pulmonary oedema—predominate. No definite chronic effects have been described. The maximum permissible concentration is 400 parts per million.

Toluene is a narcotic, and the general consensus of opinion is that it is free from the undesirable chronic effects of benzene—namely, the liability to produce agranulocytosis and aplastic anaemia. But it must be remembered that toluene may contain benzene as an impurity. The permissible concentration is 200 p.p.m. Clinical accounts of workers exposed to toluene will be found in *J. Amer. med. Ass.*, 1942, 118, 573 and 579; 1943, 123, 1106. They suggest that in concentrations as high as 200 p.p.m. some incoordination of fine movements may develop.

(2) The value of barrier creams in protecting the skin from mineral oil has been examined, and in general they were without effect (*Brit. J. industr. Med.*, 1948, 5, 204). They are probably even less effective against substances such as toluene. It will obviously be necessary, therefore, to arrange for physical protection of the skin in the factory described.

NOTES AND COMMENTS

Paroxysmal Tachycardia in Pregnancy.—Dr. E. D. KERR (High Wycombe, Bucks) writes: The "Any Questions?" section of the *Journal* (December 15, 1951, p. 1473) advises the administration of digitalis for the treatment of paroxysmal tachycardia occurring in pregnant women. There are theoretical and statistical reasons for believing that digitalis may cause foetal death. Digitalis, being a glucoside, could easily pass the placental barrier in a concentration sufficient to poison the heart of a foetus. The effect of digitalis on the foetal heart would presumably be the same as the effect on an adult heart, and a large dose would cause heart block and ventricular fibrillation. The foetal mortality rate when heart disease of the mother is present in pregnancy bears a direct relationship to the onset in the mother of cardiac decompensation and auricular fibrillation, especially the latter. The attendant impairment of circulation, with the coexisting anoxaemia, is generally considered to be the cause of foetal death, but anoxaemia is often not present to any marked extent, and other factors must be involved. One of these could be the effect of digitalis, since the drug is nearly always administered to these cases. In pregnancy the administration of digitalis is on many occasions a life-saving therapeutic measure for the mother, but it is not justifiable to employ digitalis in the treatment of paroxysmal tachycardia, since its beneficial effect on the mother may be minimal, but its detrimental effect on the foetus may be lethal.

OUR EXPERT writes: While it is possible on theoretical grounds for digitalis to have toxic effects on the foetal heart, there is no doubt of its great value in treating heart failure of pregnancy. The beneficial effect on the mother increases the chances of a live birth, and digitalis should invariably be used in the presence of heart failure, whether or not this is associated with paroxysmal tachycardia.

Dr. A. B. UNWIN (London, S.W.1) writes: In my experience attacks of paroxysmal tachycardia in persons with clinically normal hearts have been associated with excessive gaseous distension of the stomach or large intestine, cessation of an attack often being associated with the bringing up of wind. Presumably the heart is irritated by displacement upwards due to pressure from below the diaphragm. During pregnancy two possible factors could be involved. First, transmitted pressure due to the enlarging uterus, and, secondly, the effects of pregnancy hormones on the intestinal muscle tone, which tend to allow dilatation with retention of gas. An attack is usually begun as a result of a sudden movement or effort and the patient can feel it as it starts. A simple measure often effective in cutting short an attack is to take a deep breath and hold it in full inspiration; the pressure in the chest is then raised by making an effort to expel the air with the glottis closed. Other methods sometimes recommended, such as pressure over the carotid sinus or pressing the eyeballs, do not appear very effective in practice. All tight belts and corsets should be removed from the abdomen and a hot drink sipped to assist in the relief of gas from the stomach. The general treatment should be directed towards the dyspepsia. The most important single factor in the causation of abdominal distension with gas is anxiety and emotional stress, and a good general practitioner should be of help in this respect. Phenobarbitone, gr. $\frac{1}{2}$ (32 mg.) three times a day before meals, should be prescribed. Attention to diet and a warning against overeating should be given, and a glass of early-morning salts taken to prevent constipation and to assist in the general tone of the intestine and gall-bladder. Should a severe case fail to respond to these simple measures, then "prostigmin" may presumably be worthy of trial.

OUR EXPERT writes: The simple measures outlined above may be beneficial, but prostigmin is not likely to be effective unless given in near toxic doses, and should only be used after a trial of quinine and procaine amide. Anxiety is more likely to be secondary to the attacks of paroxysmal tachycardia than the cause of them. Aerophagy and subsequent eructation are also secondary to the attacks of arrhythmia rather than the cause of them: the same symptoms may be present in patients with pre-cordial or epigastric discomfort from other causes.

CONDITIONS IN FAMILY PRACTICE

INTRODUCTION

Three reports summarized below discuss different aspects of a theme that has been the subject of much debate recently. In brief, it is how to enable the family doctor to give of his best. As Dr. S. Wand has put it recently (*Supplement*, January 12, p. 9), the doctor is frustrated because he is "so often prevented from doing the best and most useful work of which he is capable."

First, a report from the Scottish Health Services Council concentrates on methods for bringing hospitals and general practitioners into closer communication. In other words, it is concerned to remove that isolation which many general practitioners have drawn attention to and attributed partly to the increase of specialization in medicine and partly to the National Health Service. Among the recommendations made is that the hospital structure should include doctors engaged partly in general and partly in specialist practice. It finds a strong case for the provision of hospital beds in which general practitioners can treat their own patients, and it emphasizes that they should have the fullest possible access to x-ray and laboratory services.

A memorandum from Birmingham Executive Council, a summary of which follows the Scottish report, agrees on the importance of a close link between hospital and general practice; it also makes suggestions for reducing prescribing costs and for introducing rules for N.H.S. patients, similar to those which existed for N.H.I. patients.

The third report is from the Leeds Division of the B.M.A. It emphasizes the lack of financial balance between the general-practitioner and hospital services and agrees that general practitioners must have hospital beds in their charge as well as free access to diagnostic services.

THE CLOSER LINK

GENERAL PRACTITIONERS AND THE HOSPITAL SERVICE

Another contribution concerned with the best ways of bringing together general practitioners and hospitals comes in a report issued by the Scottish Health Services Council.¹ The report begins by acknowledging that there is an obvious need for a closer link between the general practitioner and the hospital and specialist services. A joint subcommittee was appointed to see what could be done in this direction. The basic requirement is considered to be improved organization of general practice itself so that the doctors have more time and better facilities for the prevention of disease and

its diagnosis and treatment in the early stages. The essential basis of a comprehensive medical service is the general practice of the family doctor; therefore the general practitioner must be much more than an agent selecting patients for the nearest out-patient department.

The committee had evidence of a prevalent feeling that hospital work is becoming almost exclusively the sphere of the specialist and the hospitals themselves a preserve where the general practitioner is neither needed nor welcome. The main points of dissatisfaction are summarized as follows:

(a) The system at present adopted for the appointment of specialists, under which it is difficult, if not impossible, for the general practitioner with the requisite qualifications and experience to undertake work in a specialist capacity.

(b) The restriction of the general practitioner's part in institutional midwifery.

(c) The absence of full facilities for the general practitioner to follow his patients into hospital.

(d) The general practitioner's difficulty in gaining access to the ancillary services provided in hospitals.

Effects of Increasing Specialization

Between the two world wars hospitals increasingly looked to specialist staff for the treatment of their patients. Again, the tendency to increased specialization meant that a further line was drawn between the doctor in general practice and the doctor doing consultant and specialist work. General practice came increasingly to be regarded as inconsistent with specialist work. The committee thinks that the National Health Service has accentuated these tendencies.

Though reorganization of the hospital and specialist services was necessary, it has tended to reinforce the view that all hospital work is the province of the specialist. A closer link between the two branches of medicine would stimulate the interest of the general practitioner and keep him on his toes. The young doctor entering general practice should not find himself suddenly cut off from hospitals, where many medical advances are made and where he can obtain valuable aids to diagnosis and treatment. He must be able to feel that when he enters a hospital he is exercising a natural and acknowledged right.

Close association will also bring benefit to the patient, who will not look upon his doctor as a mere agent referring

¹Report of Scottish Health Services Council Joint Subcommittee on the General Practitioner and the Hospital Service. Membership of the Joint Subcommittee was as follows: Sir Humphrey Brown Lindsay (chairman), Professor Dugald Baird, Professor D. F. Cappel, Lieutenant-Colonel J. C. Dundas, Dr. Mary Esslemont, Dr. I. D. Grant, Dr. G. W. Ireland, Mr. A. B. Kerr, Dr. A. F. Wilkie Millar, Dr. E. Neil Reid, Dr. W. D. D. Small, Miss Eleanor Stewart, with, as secretaries, Dr. E. R. C. Walker and Mr. R. P. Fraser.

him to hospital and leaving him in the hands of specialists, but rather still as his family doctor, even though medical decisions may for a time be in other hands.

The committee reports that many doctors find themselves with a greater volume of work than they can satisfactorily tackle with justice to their patients and themselves. This was considered to be the most important factor limiting the possibilities of closer relationship with hospitals. It suggests that there is considerable scope for improvement, not least by wider provision for secretarial and other assistance. Again, the committee considers that there should be means whereby a doctor can limit his list in such a way as to have time for hospital work without loss in total remuneration.

As to administrative arrangements, it emphasizes that appointments to hospital boards should be such as to enable the interests of general practitioners to be fully and effectively voiced.

Staffing Hospitals

Reduction in number of registrar posts means that some other way must be found of carrying on the necessary hospital services. Though part-time clinical assistantships for general practitioners are welcomed, these posts should not be conceived merely to enable the less interesting work of the hospitals to be thus carried out. The committee believes that the hospital structure should include doctors wholly in specialist practice, doctors training for specialist practice, doctors engaged partly in general and partly in specialist practice, and house-officers. It points out that staffing of this kind would help to do away with the present system of training undergraduates exclusively by specialists.

There should be no barrier to part-time employment in a specialist capacity of suitably experienced and qualified general practitioners, and they should be able to apply for posts on the same terms as their hospital colleagues, the qualifications and experience being assessed by the appointing body. A general practitioner giving part-time specialist services need not necessarily be aiming at full-time specialist work, but there would be a field for him in, for example, general medicine, paediatrics, geriatrics, dermatology, anaesthetics, and ophthalmology. There is also a case for more employment of general practitioners as clinical assistants carrying out duties similar to those of registrars.

Midwifery

Many general practitioners are disquieted at the restriction of the part they may take in institutional midwifery. The committee considers that, unless there are compelling technical reasons for excluding child-bearing from the field of general practice in this central event of family life, the family doctor is the natural source of medical advice.

The distinction should be drawn not between domiciliary confinement as the province of the general practitioner and hospital confinement as that of the specialist, but between uncomplicated pregnancy as normally the province of the family doctor and abnormal as generally that of the specialist. If general practitioners are capable of supervising home confinements, it can hardly be contended that they are incapable of conducting normal confinements in hospital.

Hospital Beds

Reorganization of the hospital services under the Health Service has curtailed the facilities previously enjoyed by general practitioners, but the committee finds a strong case for the provision of beds in which general practitioners can treat their own patients. Evidence on this point submitted to the committee was on the following lines:

(a) These facilities enable the practitioner to take an active part in hospital work. He is brought into close contact with the specialist services, his range of experience is increased, and he is given a new and stimulating interest in his own work.

(b) Many of the patients admitted to hospital are suffering from conditions well within the scope of their practitioner to

treat. Large numbers of those admitted do not in fact need specialist attention, and it is uneconomic that on admission to hospital they should come under the charge of specialists.

(c) It is of inestimable value to the patient that, so far as possible, his treatment should be the responsibility at all stages of one doctor. Most patients would prefer, on admission to hospital, to continue under the care of their own doctors, who know their background and history, with whose ways they are familiar, and in whom they have confidence.

The committee acknowledges that there are certain practical difficulties, such as the time and distance involved sometimes, but it is emphatic that cottage hospitals ought to be maintained as general-practitioner hospitals. Where general practitioners have been denied access to them the policy underlying the change should be urgently reviewed. The most satisfactory scheme is to have all the doctors in the area on the staff of the hospital free to treat their patients at any time. Arrangements for admission of patients and use of beds should be left to the good sense of the doctors in association with the hospital authorities. The fullest opportunity should be taken of regular visits by specialists for consultation.

As regards other types of hospitals, the committee does not see at present anything more than a limited possibility of making beds available to general practitioners. But hospital policy should envisage the establishment of special general-practitioner wards or blocks in association with general hospitals.

X Rays and Laboratories

General practitioners should have the fullest possible access to ancillary services, especially x-ray and laboratory services. The development of radiological services ought to be related not solely to the requirements of hospital and specialist services but also to the needs of general practitioners. Though this may be a long-term policy it should be fully accepted as the basis of planning. The laboratory service for which the regional hospital boards are responsible must be conceived as an integrated service available to all branches of the profession, and every effort should be made to cater for the needs of general practitioners. The advice of consultants should be available on request. In the smaller district hospitals the general practitioner should be able on occasions to make use himself of equipment in the laboratory side-room.

As regards admitting and discharging patients, the family doctor should be kept fully informed of what is happening, and the hospital staff should give him the fullest information about his patient's condition as quickly as possible.

Finally, the general hospital ought to be a centre of medical endeavour where general practitioners have the acknowledged right of entry and where they can meet their hospital colleagues on terms of equality. Such close association would broaden the outlook of doctors in both branches of the profession. To help in bringing about this association, general practitioners should be allowed to take part in ward rounds and attend out-patient departments. Regular clinical meetings could be held, and a possibility to be considered is the organization in main general hospitals of refresher courses. Locum assistance might be provided for general practitioners from the registrar ranks of the hospital staff.

DOCTOR AND PATIENT

EVIDENCE FROM BIRMINGHAM

A memorandum from Birmingham Executive Council¹ begins by emphasizing that an important part of a general practitioner's duties should be the practice of preventive medicine and health education. This personal advice is considered likely to be more effective than

¹Prepared for consideration by the Executive Councils Association (England) in connexion with the submission of evidence to the Central Health Services Council's Committee on General Practice.

leaflets, posters, press announcements, and similar official propaganda, and in the long run it should lead to considerable financial saving.

While health centres remain a long-term policy, it is suggested that the first measure to help the family doctor should be to reduce the prescribed maximum list of 4,000 patients to the lowest possible figure commensurate with expediency and efficiency; this proposal is closely related to the problem of doctors' remuneration. The memorandum also advocates greater employment of general practitioners by local authorities in maternity and child-welfare centres.

Cost of Medicines

The memorandum draws attention to diversity of costs for prescribing between various areas of the country, and considers that it is too great. "It is apparent that in those areas where prior to July 5, 1948, the greater proportion of the population were panel patients the prescription cost is considerably lower than in the better residential areas where the majority of persons were formerly private patients." This is attributed to the fact that doctors in the more densely populated areas who were formerly prescribing *National Formulary* preparations continue to do so, and the remedy is to encourage doctors in the other areas to prescribe these preparations more. In this connexion a direct appeal to doctors by the chairman of the local medical committee could have a beneficial effect.

Consultants and hospital medical officers should be persuaded not to advise or prescribe expensive proprietary medicines, "as this is a constant source of embarrassment to general practitioners and makes it very difficult for them to resist demands."

The memorandum suggests that doctors should be notified of their average prescription costs compared with the average for the area, as they were under the N.H.I., and the public should be encouraged to buy at their own expense a reasonable supply of the common household remedies. "Finally, executive councils should always be prepared to give their official support to doctors who have resisted unreasonable demands from patients."

Bottle-of-Medicine Habit

Most doctors would agree, says the memorandum, that a considerable proportion of the mixtures prescribed for minor and trivial complaints have little intrinsic therapeutic value but often may have a beneficial psychological effect. The best cure for the bottle-of-medicine habit would be a different psychological approach, such as health education and the practice of preventive medicine. The Ministry of Health could help in this matter by disseminating suitable propaganda.

An alternative would be to impose charges for pharmaceutical services, but it is considered that this would be extremely difficult to administer in view of the numerous exceptions which would have to be made to avoid hardship.

Responsibility for Certification

"Certification has indeed become a problem for general practitioners." While it is hoped that a Ministry committee considering how to reduce the number of certificates will eliminate some, it is clear that doctors will be required to be responsible for a considerable number. The only suggestion that can be put forward at present is for adequate secretarial assistance.

Frivolous Calls

While a very small proportion of the public do make frivolous calls on doctors, it is thought that the main abuse is by people requesting doctors to visit them at home when they could attend at surgeries. "The introduction of certain basic rules for N.H.S. patients similar to those which existed for former N.H.I. patients might help to solve this problem."

Frequent Change of Doctor

The introduction of the waiting period of 14 days before people can change their doctors does not seem to have had as much deterrent effect as expected. The memorandum points out that many patients have objected to this restriction, as have a considerable number of doctors, particularly those who have started new practices. Birmingham Executive Council was opposed to the introduction of the restriction, and considers that, in view of its very limited effect, reversion to freedom to change at any time should be considered.

"It is interesting to note that the restriction on change of doctor does not appear to have resulted in any general diminution in prescribing costs or in the volume of certification, and these were the main advantages cited by the advocates of the proposal prior to its introduction."

Liaison with Hospitals and Local Health Authorities

The importance of this liaison is emphasized, and the memorandum recommends that more local medical committees should co-opt senior administrative medical officers of hospital boards. More general-practitioner beds in hospitals should be provided as a matter of urgency, particularly for obstetrics, and the memorandum draws attention to the importance of providing for general practitioners diagnostic facilities in hospitals. It suggests also that general practitioners should make more use of the out-patient clinics of mental hospitals.

Maternity Medical Services

The memorandum reports that standards for admitting general practitioners to obstetric lists vary considerably between areas. It suggests that certain national minimum standards should be formulated by a joint committee appointed by the Ministry of Health, the B.M.A., and the Executive Councils Association.

An arrangement found successful in Birmingham, which it is suggested should be extended, is for general practitioners to hold antenatal clinics out of normal surgery hours, and midwives and health visitors attend these clinics with the expectant mothers.

No Difference to Doctor-Patient Relationship

Most doctors and patients would agree, says the memorandum, that the N.H.S. has not made any material difference to the doctor-patient relationship. Extremely few complaints have been received by executive councils, but unfortunately when they are investigated by medical service committees the publicity they receive has tended to magnify them out of all proportion to the general satisfaction which the vast majority of the public receive from their doctors.

It is believed that only a negligible number of N.H.S. patients have decided to become private patients, and that many of the small percentage of people who started by being private patients are registering with doctors under the N.H.S.

WHAT IS WRONG WITH THE N.H.S.?

FAULTS ANALYSED BY LEEDS DIVISION

The Health Service shows a lack of balance between preventive and curative medicine.

Preventive medicine and research are relatively neglected in comparison with curative services.

Too much money is being spent on the hospital services and too little on the general-practitioner services.

These are some of the conclusions that the executive committee of the Leeds Division of the B.M.A. came to after a series of meetings held last winter to discuss the Health Service. Invited speakers at the meeting included distinguished laymen as well as medical men in the main branches of the profession.

Discussing the lack of a preventive outlook in the N.H.S., the committee points out in a summarized report that there is only one medical officer of health on any of the 14 regional hospital boards.

High Administrative Costs

The committee condemns the excessive centralization of power in the Health Service and also the present powers of the Minister to issue regulations. Much money is wasted because hospital management committees have no incentive to save, administrative costs are high, and there is often failure to take advice from doctors in close touch with hospital and patient.

The committee says that many doctors regard the disappearance of medical officers from large hospitals as a retrograde and expensive step. And it is not in the national interest that restriction of the general practitioner's work, the lowering of his status, and the excessive work he has to do should continue. The public attitude to "free doctoring" needs changing by education, and private practice should not be allowed to die out lest the orthodox treatment of disease should rest in the hands of a medical State monopoly.

The N.H.S. as seen by patients and doctors was discussed by the committee, and some of its conclusions are given below.

The Patient's View of the Service

State patients find the Service a great financial relief, but fear that medical overwork may lead to an impersonal Service. Most of them would prefer to have minor operations performed at home or in their own doctor's surgeries. While still wishing the general practitioner to be a "real family friend," they have a somewhat exaggerated idea of the value of hospital services and investigations.

Private patients feel that it is wrong they should have to pay for medicines and prescribed appliances when they contribute to the scheme, and strongly resent having to pay the whole cost of upkeep of a private bed in hospital.

The General Practitioner's View of the Service

Most general practitioners in the Service work harder with less financial reward than formerly. Private practice, which had always subsidized panel practice to a variable extent, has now virtually disappeared.

The status of the G.P. has fallen, and the scope of his work is increasingly restricted. The progressive exclusion of G.P.s from cottage hospitals and the virtual abolition of general-practitioner consultants are bitterly resented. Apparently there is to be no place in the hospital for him, although his right to treat suitable cases there has always been conceded in theory. General practitioners should have the right to treat their own patients in specially provided hospital beds.

An immediate need is the provision of a good pathological service; all speakers agreed that free access to diagnostic facilities was vitally necessary. This would enable general practitioners to treat many cases now admitted to hospital for expensive investigations.

The committee members were unanimously in favour of such changes in remuneration as would allow general practitioners to give a high standard of service, and yet allow them reasonable leisure. In practice this would mean a progressive diminution in the maximum permissible number of patients on a doctor's list accompanied by a simultaneous rise in the capitation fee.

Doctors employed by hospital boards and coming under the National Health Service superannuation scheme can remain under this scheme if, within twelve months of ending their hospital board appointment, they become employed by a medical school or the Medical Research Council (except the Public Health Laboratory Service). An explanatory circular (R.H.B. (52) 1) has been issued by the Ministry of Health explaining doctors' superannuation rights under these arrangements.

N.O.T.B. ASSOCIATION

The N.O.T.B. Association held its nineteenth meeting on December 14, 1951, when reports from all the subcommittees were adopted. It was noted that the Ophthalmic Group Committee viewed sympathetically the resolution

That the D.O.M.S. should not be required for posts below the grade of registrar and that the British Medical Association should be asked to exclude such advertisements from the *British Medical Journal*;

and that the matter had subsequently been approved by the Consultants and Specialists Committee and the Council of the British Medical Association.

Future Eye Services.—The special *ad hoc* committee reported its general views, and a special meeting of the committee has been called early in January to formulate practical proposals.

Memorandum and Articles of Association.—After making various recommendations the draft memorandum and Articles of Association have been approved and will be circulated to all members with the annual general meeting agenda. It was decided to invite the legal representative to attend the meeting to deal with any specific inquiries which might be raised.

Locumtenents.—The Committee took the view that the appointment by an ophthalmic medical practitioner of a locum to attend N.O.T.B. medical eye centres for a longer period than three months, which covered normal difficulties, was undesirable, and that the Committee should be advised where it was necessary to extend this period.

"Small Corrections."—Proposals regarding the method by which ophthalmic services committees should deal with queries on "small corrections" were considered. It was decided to pass these recommendations to the Ophthalmic Group Committee as a fair and practical solution of the problem.

"Non-tolerance" Cases.—The Committee had two cases before it in which medical members had been asked to agree to a reduction of their fees to reimburse the cost of reglazing frames and, in the one case, the second examination fee. It was decided that as so important a principle was involved, and that as the Ophthalmic Group Committee was also considering this problem, further discussion should be held over pending the views of the Ophthalmic Group Committee being available.

Storage Problem for Supplementary Ophthalmic Service Records.—The problem of storing old supplementary ophthalmic service records by executive councils was mentioned, and the Committee came to the conclusion that a practical solution would be to retain records for three years, which was considered a reasonable period for the life of a frame and lenses.

SUPPLEMENTARY OPHTHALMIC SERVICE CENTRAL OPHTHALMIC LIST

Under section (b) of the revised criteria for admission to the Central Ophthalmic List (see *Supplement*, October 6, 1951, p. 130) it is laid down that "six months shall have been spent in a resident appointment." This has been mistakenly interpreted to mean that appointments in hospitals where no resident facilities are available cannot be counted.

Therefore the approval of the Ministry of Health has been sought to the addition of a suitable phrase on the application form to include such appointments. The Ministry has now agreed that, for the purpose of satisfying the qualifications for the Central Ophthalmic List, six months spent in a resident hospital or in a whole-time non-resident appointment of equivalent status shall be taken into consideration by the Ophthalmic Qualifications Committee.

An appropriate amendment of the National Health Service (Executive Councils) Amendment Regulations, 1951, will be made as soon as possible.

OCCUPATIONAL HEALTH COMMITTEE

NATIONAL COAL BOARD AGREEMENT

A fully attended meeting of the Occupational Health Committee was held at Headquarters on January 9, with Dr. J. A. L. VAUGHAN JONES in the chair. It was reported that Professor R. C. Browne had accepted an invitation to join the Committee in place of Dr. Donald Stewart, resigned, that Dr. H. F. Hollis had been appointed as representative of the General Medical Services Committee, and that Dr. J. M. Rogan had agreed to serve as a co-opted member. The new members were welcomed by the Chairman. The Committee devoted some time to the reminder from the Council of the need for economy in the summoning of meetings and in the circulation of documents. It was decided that wherever possible the subcommittees should meet on the same day as the meeting of the main Committee.

The CHAIRMAN reported that he and two other members of the Committee had met representatives of the National Coal Board to discuss the Association's claim concerning remuneration of whole-time medical officers employed by the Board. The meeting was a very agreeable one, and the results were good. The proposals as now agreed were published in the *Supplement* of December 15, 1951, p. 263.

The remuneration of part-time medical officers employed by the Coal Board was reported to be still under consideration. In addition discussions would begin in the near future regarding compensation payments for death or disablement by medical practitioners undertaking duties for the Board.

Negotiations on Salary Scales

Dr. J. B. WRATHALL ROWE moved that in view of the favourable outcome of the negotiations with the National Coal Board the Committee should give further consideration to negotiating salary scales with other employers on a nation-wide basis. He was aware that about a year ago the Committee decided that it could negotiate only if it were approached by the medical officers of the industries concerned. He thought the Committee should now reconsider the situation.

Several members expressed opposition to the proposal on such grounds as that some industrial medical officers might not wish to have their salaries negotiated by the Association, that such negotiations might place them in an invidious position, that negotiations would take a long time and might delay normal increases, and also that there was no single body which represented all the nationalized industries. The Confederation of Employers was not a negotiating body; negotiations were undertaken by groups of employers in single industries. After further discussion Dr. Rowe withdrew his resolution.

Occupational Dermatitis

Dr. H. ALEXANDER, chairman of the subcommittee, reported on the matters which have been under consideration. The subcommittee recommended the revival of the practice of referring cases of occupational dermatitis to an examining medical practitioner appointed for the area in which the claimant was employed (not necessarily the one in which he was resident), and an arrangement for automatic reference to a dermatologist of all cases of occupational dermatitis persisting after 21 days, a copy of the dermatologist's report to be sent to the examining practitioner.

The CHAIRMAN complimented Dr. Alexander on the way in which his subcommittee had handled a long-standing and somewhat confusing problem. It seemed to have arrived at a clear decision. It was agreed that, subject to an answer to certain questions from the Ministry of National Insurance, the representations proposed should be made to the Ministry and that it be recommended that every effort be made to secure a closer liaison between the Factory Department of the Ministry of Labour and the Ministry of National Insurance.

A brief discussion took place on the method of appointing the examining medical practitioners. It was the general feeling that a man who had shown himself to be an able practitioner should be selected, not necessarily a man with special dermatological knowledge. It was also suggested that the Dermatologists Group might consider the suggestion that appointed factory doctors might act as clinical assistants to dermatologists.

Other Business

A proposal which had been made to summon a Conference of Joint Councils of Industrial Health, to be held in London in 1952 under the auspices of the B.M.A., was deferred for another 12 months.

The Committee supported a recommendation of the Science Committee that the Mackenzie Industrial Health Lecture be given as part of the provincial meeting of the Association of Industrial Medical Officers in Liverpool in July, 1952, and that Dr. Donald Stewart be invited to lecture on "The Future Development of Industrial Medicine."

A question raised by a member of the Association that senior industrial medical officers should be considered particularly suitable for admission to Medical Appeal Tribunal panels was referred for an opinion to the Central Consultants and Specialists Committee.

Various matters, including the question of car allowances for industrial medical officers, were left over to the next meeting.

PARTNERSHIP IN N.H.S.

SCOTTISH GUIDANCE

Advice on partnership problems for doctors practising in Scotland is given in a memorandum prepared by the General Medical Services Subcommittee (Scotland) and issued by the B.M.A. Scottish Office. It is published as a pamphlet called *Medical Partnerships Under the National Health Service (Scotland)*.

The Subcommittee emphasizes that its advice should not be regarded as replacing legal advice on the actual drawing up of a partnership agreement. The memorandum covers many of those intricate problems that beset partnerships. These include various types of financial arrangement, what should be included under expenses, the effect of partnership on superannuation, termination of partnership, and restrictive covenants. Doctors thinking of going into partnership in Scotland are advised to consult the memorandum, copies of which may be obtained from the Scottish Secretary, B.M.A. Scottish Office, 7, Drumsheugh Gardens, Edinburgh.

MEDICAL SUPERINTENDENTS' ARBITRATION

The medical superintendents' claim for higher remuneration was heard by the Industrial Court on January 8 and 9. It was presented by Mr. K. Diplock, K.C., and Mr. S. B. R. Cooke.

According to a statement from the Association of Optical Practitioners, there is a "marked revival of the fraudulent activities of unqualified eyesight quacks who canvass from door to door in country districts." Some people are also said to be buying ready-made spectacles at chain stores. These two dangerous practices had been almost eliminated by the introduction of the Health Service, "but since the changes which took place last May there appears to be a misunderstanding of the present position by some people, who as a result fall prey to the wiles of the itinerant quack." The statement then points out that no charge is made for sight-testing, no doctor's certificate is necessary except for the first sight test, and, while only children and persons ill in hospital can now get spectacles completely free, the new charges usually do not exceed 30s.

Correspondence

Standards of General Practice

SIR,—I have followed the correspondence in full concerning a proposed College or Faculty of General Practice with interest. The diagnostic unit described by Dr. John H. Hunt (December 29, 1951, p. 1575) can of course provide only for private patients, and while these still exist in good supply in London they are a very diminishing quantity with present taxation and redistribution of the national income. Such a high standard of medical care is ideal, but is not what is envisaged or required by the Ministry of Health.

Three and a half years ago it was decided to spend the major portion of the money available for the National Health Service on hospital and consultant services; dentists, opticians, and chemists. Remuneration of doctors was to remain low, so that the work undertaken by a general practitioner was consequently to be of the lowest possible order. Everything was to be sent to hospital, and in consequence those of us who see both worlds observe "letters" requiring the provision of a D-amphetamine course for supposed obesity, or the patient's name put on an E.C.10 form, with the words "Cough, please see," underneath. This is the standard of care that is apparently required, and it is sad to those of us who would, and could, do so much more for our patients if we were paid a little more money.

Three and a half years have gone by, and the Ministry has spent it in evasive procrastination concerning remuneration, and even has the face to decide to inquire what doctors' incomes are, having itself, through executive councils, paid over the Treasury moneys of their incomes and virtually eliminated private practice in most parts of the country. On top of this we are offered arbitration, the outcome of which in the dim, far future will be that doctors will probably receive even less than at present. The recent figures in the *Journal* showed that the average gross income of the doctor in London and Glasgow was £1,300 to £1,400, while the dentists received an average of £4,000 gross. The decision has been made, and general practice is to be for generations the lowest-paid branch of the profession.

The present enormous number of students are heavily subsidized in their studies by local authority and Government grants. Most, who will enter general practice, will have to endure life on a housing estate and a gross income of £1,300 a year. They will, of course, be exceedingly lucky to get themselves established at all, either in general practice or elsewhere, considering the large numbers of applicants for any practice vacancies or hospital appointments.

Much as I applaud the efforts of Dr. Hunt to raise the standard of general practice, I feel he and others ought to know that he is trying to achieve the impossible in face of the policy of the Ministry of Health. Should there ever be any serious effort to improve the lot of the general practitioner, the scheme proposed by the Medical Practitioners' Union is the only possible solution. By this, the capitation fee would be uniform, but most of the expenses, as agreed by the Tax Commissioners, would be met out of a separate fund. This would eliminate the anomaly that at present expenses vary from practice to practice throughout the country, and even account for 80% or more of the gross income.

While we discuss whether private patients can have a grant-in-aid for private hospital accommodation or free medicines we shall get nowhere. If such a proposal was granted it would be logical for those of us who wish to send our sons to Eton to demand a grant-in-aid, so that we need only pay the difference between the cost of a public school and the cost to the State of the village school, or the difference between a senior university and the local polytechnic. Such a proposal will obviously never be countenanced by the Treasury.—I am, etc.,

London, W.2.

P. F. KENNISH.

Payment by Capitation Fee

SIR,—Payment by capitation fee may not be as stupid as Dr. J. Richardson (*Supplement*, December 22, 1951, p. 284) tries to make out. More than half the illnesses that come to a general practitioner are avoidable and are mainly due to the shortcomings of the patient. If it is made clear that the person primarily responsible for his health is himself—that most tuberculosis, pneumonias, colds, etc., are due to a lowered resistance of the body, that this is mostly built up by adequate hours in bed (which few get), that most neurosis and diseases such as gastric and duodenal ulcers are made worse, if not caused by, a failure to have a satisfactory philosophy of life—then folk will begin to realize that it is up to themselves, rather than the doctor, to keep themselves fit and well.

There is no space here to enlarge on the manner of dealing with each complaint; but to those who for years have taught health education, rather than allowing the patient to think that it is the doctor who gives them health or makes them well, payment by capitation fee brings a just reward.

Those who have brought up patients to believe that a course of injections, or frequent visits, will cure them will rightly be expected to continue giving courses of injections—and frequent visits.—I am, etc.,

Pettswood, Kent.

G. C. MILNER.

Two Grindstones

SIR,—At the moment two separate working parties are considering the conditions of general medical practice. It seems to me that the general practice side of the profession is afflicted with its usual muddleheadedness. Part I Sect. 1 (1) of the 1946 Health Act requires that "it shall be the duty of the Minister of Health . . . to promote the establishment . . . of a comprehensive health service. . . ." Presumably the Ministry knows what sort of service it wants. Would it not be much wiser for the general practitioners to elect to be paid on a part-time sessional basis as in para. 5 of the terms and conditions of service for hospitals? They could then provide the public with the sort of medical care the Ministry requires at such hours and times as they would undertake, all necessary accommodation and ancillary services to be provided by the Ministry, preferably at some distance from the doctors' official place of employment. They could then provide the public on a fee-paying basis with the sort of service it wants. Only in some such way can they escape from a position between two grindstones.—I am, etc.,

Nelson, Lancs.

OWEN WILSON.

Pirating of Practice Premises

SIR,—In the *Supplement* of December 22, 1951 (p. 285), it is stated by a correspondent that in the days of free market of practices a practice was never bought without the house or surgery from which it was carried on, and that it was understood that there attached to the house part of the goodwill which the doctor paid for. Then follows the astounding statement, "Nowadays the outgoing doctor gets compensation at the same rate as would attach itself to an ordinary sale of a practice." Another correspondent (p. 286) declares that "the owner of the premises . . . should be obliged to sell or rent them to the successor to the goodwill" (which incidentally was, one understood, one of the evils that Socialism had abolished).

When I bought my share of a partnership in 1919, paying for it out of my earnings, there was no house attached, and this I had to arrange for independently. In due course by careful thrift I was able to buy the house, regarding this and my practice as capital assets against the time, now not far off, when my working days must cease. Up to 1948 I had frequent offers to purchase my practice at two years' purchase and my house at the current valuation.

Now, when I retire I shall get some as yet unspecified compensation for my practice, which I understand is likely

to be less than one and a half years' purchase, while drawing from that undetermined sum the meagre interest of 2½%, some of which may no doubt have to be repaid: And yet this forced and to me unprofitable confiscation of my practice, according to your correspondents, should oblige me to sell my house to some individual whom I do not know on the instruction of some committee whom I shall most certainly despise.

In my opinion all the ills that the profession is now suffering from, including the degradation of general practice, and all those matters which are now so hysterically under discussion for amendment, are directly due to the abject surrender of 1948. Then was the time to insist on amendment—when the B.M.A. had the swashbuckling Minister at its mercy, when, to paraphrase himself, this bladder of verbosity could have been drained by a timely sweep of the scalpel of unity. But suddenly and inexplicably the surgeon dropped his instruments, doffed his gloves and gown and mask, and in tremulous tones said, "Sorry, Right Honourable Sir, you win," and left the theatre. Hence the frequency and foulness of our profession's symptoms to-day.

As for my own house, I still regard it as my own property, and I do not consider that I stand under any obligation in regard to it in relation to the "State" or to my profession. Its value has appreciated not as much as the value of sterling has diminished.

I have paid material fees for the assessment of its development value, the compensation for which will be practically worthless. It has a definite value as business premises, and as such it shall be sold to the highest bidder. But under no circumstances, unless forced by further erosions upon our professional liberty, which we could if we would but have hitherto shown ourselves contemptibly unable to resist, will I suffer the humiliation of applying to one of these interminable committees, and risking all the possible pains and penalties written into the Act around such a transaction, and sell it to a medical practitioner, pirate or otherwise.—I am, etc.,

Minehead, Somerset.

H. B. WALKER.

Representation of Doctors

SIR,—There is among general practitioners a growing sense of grievance about the slowness of negotiations with the Government over the settlement of our remuneration. Many sections of the community have had wage claims settled by the Government in a matter of weeks, and other professional bodies and business men have been able to adjust their expenses to meet the rise in the cost of living.

Every week letters are written to the *Journal* about matters vitally affecting our future. Apart from the question of remuneration, there have been recent letters about conditions of service under the N.H.S., assistants unable to find employment, overcrowding in the profession, and the control of the number of students entering medical schools.

There are at present only two methods of expressing our views. The first is by letters to the *Journal*. The second is by means of local B.M.A. meetings, through our representatives on numerous committees, and so to the notice of the Government.

I suggest that many of our present troubles spring from our present method of representation, which is slow in ascertaining the wishes of general practitioners and slower still in taking effective action. The alternative is paid whole-time representation. If every practitioner would be prepared to make an annual contribution of five pounds, then groups of 500 doctors could have a chosen representative, and 40 would cover the interests of all those at present in practice. Such a representative could maintain personal contact with every doctor in his group, be always available for consultation, and spend the necessary time representing our interests on committees. By such an arrangement the feelings of general practitioners could be ascertained on any issue and co-ordinated action taken in a few weeks. Not only would practitioners then feel that their interests were properly represented, but the Government would be much

more inclined to take notice of a section of the profession which they would know was effectively co-ordinated and represented.—I am, etc.,

Sittingbourne, Kent.

K. W. HARDY.

Car Sign

SIR.—Why in these enlightened times is it considered bad form for medical practitioners to have some method of warning in their cars to the effect that they are on an urgent visit, the delay of which may very possibly cost a life or, at any rate, considerable deterioration of a patient's condition? I do not mind admitting that on several occasions I have simply accepted the responsibility and broken through the red light traffic control, but in doing so there has been no indication to other drivers of the urgency or legitimacy of my purpose.

I realize that various arguments may be brought up against having a bell or other warning signal in doctors' cars, the chief of which may be that it could be used unnecessarily. However, it would be quite easy to attach as a condition to using one of these warning signals a police regulation prohibiting its unnecessary use. The argument may be put forward that the number of vitally urgent visits is not very high. My only rejoinder to this is that, living beside a busy traffic crossing, one very soon realizes what a comparatively large number there are throughout the normal working year, especially since one is often on duty for a week-end for a group of perhaps eight or more doctors—i.e., at risk for perhaps 20,000 patients.

The B.M.A. badge which was recently introduced is no doubt a help, but it is not visible at night and is very probably not yet recognized by the public at large. To make allowance for our hypersensitivity already mentioned, it might even be possible for an enterprising firm to produce an illuminated "doctor" sign which could be displayed behind the windscreen only when the urgency of the occasion demanded—i.e., working on the principle of all direction signals, only placed inside the car and suspended from the roof interiorly.—I am, etc.,

Wembley, Middlesex.

M. E. ARNOLD.

Cost of Prescribing

SIR,—I, along with the majority of practitioners, am anxious to co-operate in cutting down costs in prescribing where this can be done without detriment to the treatment of individual patients.

Both the constant flow of circulars through the post and advertisements in the medical press virtually never mention the price of the preparations advertised but simply supply vague information such as "available on Form E.C.10." It may well happen that of two preparations which one knows to have equal clinical effect one is cheaper than the other.

I would suggest that it is thoroughly unsatisfactory, and against the interests of normal commercial competition, that prices are deliberately withheld. I believe that a majority of practitioners would agree to a proposal that you should accept no advertisement on which, where it can be readily done, prices are not clearly stated. I would suggest that this policy should be adopted.—I am, etc.,

Bath.

A. DAUNT BATEMAN.

No Further On

SIR,—In the *Supplement* of December 15, 1951 (p. 263), I note that the National Coal Board after discussion and in agreement with the B.M.A. has agreed to raise the rates of pay for full-time medical employees of the Board from £1,250 to £1,900 per annum for area medical officers and from £1,700 to £2,300 for divisional medical officers. The method of negotiation must have been very different from that adopted in trying to get an adequate remuneration for G.P.s.

It seems that, as soon as the G.P.s—also Government employees since July, 1948—ask for a rise in wages the Government in agreement with the B.M.A. requires all kinds of statistics about G.P.s and promises that G.P.s will do and not do many things. How comes it that the rise in the cost

of living is valid for increase of pay to everyone but G.P.s? Why is everyone else entitled to more pay for more work except G.P.s?

For nearly three and a half years we have been State employees, but for some inexplicable reason or reasons our rate of pay tends to go down instead of up. For many years we have been living and working in a state of negotiations which go on for ever and never produce anything but more duties for the G.P.s and more work. Surely there must be something fundamentally wrong somewhere which neither the B.M.A. nor the Fellowship for Freedom in Medicine nor the Medical Practitioners Union seems competent or able to deal with. What's wrong? Until we find out we shall always be underpaid and overworked.

For forty years our representatives have been negotiating for better pay, first under N.H.I. and now under N.H.S., and we are practically where we were in 1912 as regards remuneration.—I am, etc.,

St. Osyth, Essex.

R. E. CLARKE.

Appointment of Consultants

SIR,—May I trespass on your space to reply to Mr. A. Eric Wilson's letter (*Supplement*, December 22, 1951, p. 285)? He appears to be under a misapprehension on two important matters.

I would not suggest that, as a rule, a clinical assistant should do the work of a consultant in an out-patient clinic. However, with the present need for economy in the Health Service and having regard to the fact that the great majority of out-patients at the hospital in question are old cases, I submit that for this hospital a consultant with a clinical assistant could adequately cover the whole of the work.

In an adjoining region an ophthalmic consultant sees all the new cases and looks after all in-patients, and a clinical assistant sees a proportion of the old cases. This arrangement apparently works smoothly, and the clinical assistant in question is provided with a hospital post suited to his ability. Without this, he would have no hospital work, much restricting his scope as an ophthalmologist.

With regard to his final point, Mr. Wilson says that the appointment was made on the recommendation of those who knew all the facts regarding the local situation and the needs of the area. In answer to this, I would remind him that the medical staff and management committees most closely concerned had supported the candidature of the now displaced ophthalmologist, who had actually done the work for two and a half years. Further, the three other ophthalmic consultants in the clinical area were never consulted about the advisability of introducing a new consultant into the area.

These two facts are hardly consistent with the last paragraph in his letter.—I am, etc.,

R. J. BUXTON.

Practice Compensation

SIR,—The news that general practitioners are to receive a compensation figure of approximately one and a half times the annual value of their pre-nationalization practices must surely be the final proof of the ineptitude of the B.M.A. as a negotiating body on their behalf. I have searched the pages of the *B.M.J.* for an editorial lead or at least some indication of protest against this grossly inadequate figure, but as yet in vain.

If my memory serves me correctly, one of the main baits held out to ensnare G.P.s into the Health Service was the fact that we were to receive £66m. by way of compensation. At the time it appeared that about 18,000 G.P.s would take part in the scheme, and it was calculated by several competent actuaries in our midst that we could expect to receive just over twice the annual value of our practices.

I take it that the B.M.A. is cognizant of the fact that a fair percentage of G.P.s purchased their practices before the world war at the rate of two years' gross takings, when the purchasing power of the pound was at least double its present-day counterpart. The majority of these unfortunate practitioners will never be able to afford to retire, and

ipso facto they will die, before they are in receipt of their compensation.

It would appear, therefore, that another barefaced swindle is about to be perpetrated at the expense of the luckless G.P. When will we rouse ourselves from our apparent apathy and put down this tyranny of victimization which is grinding general practitioners into the dust and dregs of the medical profession? When will we cry, "Enough. A new deal for the G.P. or we resign"?—I am, etc.,

North Wingfield.

H. FIRMAN.

POINTS FROM LETTERS

Large Lists

Dr. RALPH A. A. R. LAWRENCE (Leabrooks, Derby) writes: May I reply briefly to Dr. H. J. Pratap (*Supplement*, December 8, 1951, p. 259)? The area in which I am practising is not adequately served already by the six existing practices. It is a mixed urban and rural area and was advertised by the executive council as a vacancy and was also classified by the Medical Practices Committee under Schedule I at that time. It is worth pointing out that in the last M.P.C. survey this area is still under this classification (*Supplement*, October 27, 1951, p. 182). Moreover, if it were adequately served by existing practices, why are patients changing over to my list? This brings me to Dr. Pratap's question about where my patients are coming from. I maintain that patients change because: (1) They are dissatisfied with the treatment they have received hitherto. (2) Greatly inflated lists prevent them from being treated adequately. (3) Situation of the surgery is convenient. (4) They are "frequent changers." As I pointed out in my letter (*Supplement*, October 27, 1951, p. 186) No. 4 has not applied to my practice as yet. Obviously, therefore, the first three are the operative factors. As regards assistants, Dr. Pratap (*Supplement*, October 6, 1951, p. 140) makes saints and martyrs of the established practitioners and demons of the assistants. Dr. Pratap gives one the impression that the established practitioner wants to hold all the aces and all the trumps.

* This correspondence is now closed.—Ed., *B.M.J.*

Succinct Address

Dr. T. DAVID LAMBERT (Ruislip, Middlesex) writes: For some years now I have been seeking some sign that the B.M.A. hierarchy was remotely aware of the problems of the general practitioners. I was delighted to read the address by Dr. S. Wand (*Supplement*, January 12, p. 9). These are the things that all general practitioners are feeling so acutely. The whole address is a succinct distillation of the frustrations we are experiencing. It should be placed in a prominent position at every headquarters of executive councils and local medical committees. Dare we hope that Dr. Wand's words will be heeded? If they are not, then surely the rank and file must soon rebel and throw out their present leaders.

Tracing Patients

Dr. R. A. MOREA (Ilford, Essex) writes: Regarding the purge that is being carried out on doctors' lists, I would like to register some protest on two points. (1) Who gets the benefit of the capitation fee of patients who have left their addresses and not yet transferred to another doctor, say, in the same district? It seems most unfair that their names should be removed from the doctor's list. They might not need the services of a doctor for some years and yet be still on his list at a new address. (2) It seems an imposition on the doctor to carry out the work of the executive council without some recompense for time, labour, and extra mileage done. I have already visited some addresses three times without anybody being present at the address.

Dr. T. W. S. PATERSON (Haddenham, Bucks) writes: In the contract we signed I do not remember any clause that we were to do messenger work at the instance of the executive council. I received a notice to forward an M.R., as the man was dead. It so happened that, a few days before I received the notice, he came to me for authority for glasses. Previous to that I had not seen him for nine years. I returned the M.R. and rang the clerk and asked him upon what authority he informed me this patient was dead, pointing out how serious the consequences for the dependants might be when the man did actually die. He informed me that the information came from the food office. When I expressed surprise that a statement of that import was accepted from . . . that office, he replied that those were his instructions. It will be noted that if we do not do this messenger work we are mulcted of 16s. . . . A certain number on my list are removed because there is no reply. In at least two cases the patients deny ever having received the request. It is not extended time

we want, but the imposition of this indignity removed. Our bureaucrats must know that petrol is 3s. 7d. a gallon, and we have a good deal to do without useless journeys and knocking at doors which are not opened. It is quite a common thing to receive no answer from the council house and the ones on either side of the "dead" patient. The children are parked at school and the parents are working.

B.M.A. LIBRARY

The following books have been added to the Library:

- American Medical Association: *Primer on Fractures*. Sixth edition. 1951.
- Barnford, F.: *Poisons*. Third edition revised by C. P. Stewart. 1951.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: P. I. Boyd, M.D., M.P.H., Medical Officer Grade B, Health, Trinidad; E. F. B. Forster, M.B., Ch.B., Specialist (Psychiatrist), Gold Coast; W. T. M. Gilbert, L.R.C.P.&S.I., L.M., Assistant Director of Medical Services, Gold Coast; A. C. Howard, M.B., B.S., Senior Medical Officer in Charge, Zanzibar; W. G. Wolfe, M.D., and P. E. A. Blake-Knox, M.B., Ch.B., Medical Officers, Tanganyika; R. S. Jelliffe, M.B., B.S., and E. M. R. Stuart, M.B., B.Ch., Medical Officers, Nigeria; K. L. Batten, M.B., B.S., and H. A. Karrach, M.B., B.Ch., Medical Officers, Uganda; C. Cywinski, M.B., Ch.B., and B. V. Hassan, M.B., B.Ch., Medical Officers, Federation of Malaya; W. J. D. Eherlie, M.B., M.R.C.P., Special Grade Medical Officer, Nvasaland; J. C. Bryce, M.B., Ch.B., Medical Officer, Sierra Leone; H. S. Kinman, L.R.C.P., Medical Officer (temporary), Nigeria; J. S. B. Pogonowski, M.B., Ch.B., Assistant Medical Officer (temporary), General Hospital, Bahamas; L. R. Roberts, M.B., Medical Officer, Gold Coast; A. S. Szurkawski, M.B., Ch.B., Temporary Medical Officer, Nigeria.

The Secretary of State for Scotland has appointed the following five new members to the Scottish Health Services Council in place of those who retired on December 31, 1951: Bailie J. W. Hyslop, member of Dumfries County Council and Executive Council; Bailie J. McAslan, Convener of Glasgow Health and Welfare Committee; Dr. P. K. McCowan, Physician Superintendent, Crichton Royal, Dumfries; Mr. A. A. MacIver, C.A., F.H.A., Secretary and Treasurer, Board of Management for Glasgow Royal Infirmary and Associated Hospitals; and Mr. G. M. C. Stewart, Vice-chairman, Pharmaceutical General Council (Scotland). The following members have been reappointed: Professor DUGALD BAIRD; Dr. W. G. CLARK; Dr. MARY ESLEMONT; Miss E. G. Manners, R.G.N.; Dr. A. F. WILKIE MILLAR; Mr. T. Rankin, L.D.S.; and Professor Sir SYDNEY A. SMITH.

Association Notices

PRIZE ESSAY COMPETITION FOR MEDICAL STUDENTS, 1952

The Council of the British Medical Association is prepared to consider the award, in 1952, of prizes to medical students for essays submitted in open competition. The subject of the essays shall be: "The Training of a Student in the Personal Relationship Between Doctor and Patient."

The purpose of this competition is to promote systematic observation among medical students. In awarding the prizes *due regard will be given to evidence of personal observation*. No study or essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. A prizewinner in any year is not eligible for a second award of the prize.

Any medical student who is a registered member of a medical school in the United Kingdom or the Colonial Empire at the time of submission of the essay is eligible to compete for a prize. If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award will be made. In determining the number and amount of prizes to be awarded, the Council will take into consideration the number of essays received. In 1951, 42 essays were received, and a first prize of £75 and two second prizes of £50 each were awarded.

It is suggested that essays should consist of from 2,000 to 5,000 words. Essays must be typewritten or legibly written in the English language on foolscap paper, on one side only, must be unsigned, and must be accompanied by a note of the name and medical school of the entrant. Notice of entry for this competition is necessary, and a form of application can be obtained from the Secretary of the British Medical Association.

Essays must be forwarded so as to reach the Secretary of the British Medical Association not later than January 31, 1952. Inquiries relative to the competition should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

PRIZES FOR NURSES

The Council of the British Medical Association is prepared to consider the award in 1952 of prizes of the value of 20 guineas for the best essay, and 10 guineas for the second best essay, submitted in open competition by each of the following categories of nurses: (1) student nurses; (2) State-registered nurses working in a hospital; (3) State-registered nurses not working in a hospital (i.e., district nurses, private nurses, etc.); (4) State-enrolled assistant nurses.

The subject of the essays for 1952 are:

Category 1.—"Why did you decide to take up nursing? Why do you think some nurses give it up?"

Category 2.—"What can be done to make the most efficient use of trained nursing staff in hospitals, with special reference to the avoidance of wastage?"

Category 3.—"Discuss the risks of conveying infection in the course of your work and the steps you would take to prevent it"

Category 4.—"The nursing care of the incontinent patient."

The purpose of these prizes is the promotion of systematic observation among nurses. In awarding the prizes *due regard will be given to evidence of personal observation*. No essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize.

Nurses who are undergoing a course of training at a hospital are eligible to compete under category (1); nurses registered by the General Nursing Council are eligible to compete under categories (2), (3), or (4), whichever is appropriate.

If any question arises in reference to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. Should the Council decide that no essay entered is of sufficient merit, no award shall be made.

The essay should be typewritten if possible, but a legibly written manuscript will receive equal consideration. It must be written in the English language, unsigned, and have attached to it a note containing the name and address of the

candidate and the category into which he or she falls. Essays, which it is suggested should consist of 2,000 to 5,000 words, must be forwarded so as to reach the Secretary of the British Medical Association not later than March 31, 1952.

Preliminary notice of entry for this competition is required, and a special form for this purpose is obtainable from the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

Diary of Central Meetings

JANUARY

- 22 Tues. Staff Side of Committee C (at 1, Richmond Terrace, Whitehall, S.W.), 10 a.m.
- 22 Tues. Whitley Committee C (at 1, Richmond Terrace, Whitehall, S.W.), 12 noon.
- 22 Tues. "Dual Appointments" Conference (at 1, Richmond Terrace, Whitehall, S.W.), 3.30 p.m.
- 23 Wed. Council, 10 a.m.
- 23 Wed. Staffing Committee, 1.40 p.m.
- 24 Thurs. Subcommittee *re* Arbitration on Remuneration of General Practitioners, General Medical Services Committee, 10.30 a.m.
- 24 Thurs. Registrars Group Executive Committee, 2 p.m.
- 25 Fri. Venereologists Group Committee, 2.30 p.m.
- 28 Mon. Psychological Medicine Group Committee, 2 p.m.
- 31 Thurs. Education Conference Subcommittee, International Relations Committee, 10.30 a.m.

FEBRUARY

- 1 Fri. Committee *re* Fees for Part-time Work under Local Authorities, 2 p.m.
- 6 Wed. General Practice Review Committee, 11 a.m.

Branch and Division Meetings to be Held

ENFIELD AND POTTERS BAR DIVISION.—At Firs Hall Ballroom, Green Lanes, Winchmore Hill, N., Wednesday, January 23, 7.30 for 8 p.m., annual dinner of Enfield Medico-Ethical Society and first annual dinner of Enfield and Potters Bar Division to be held jointly.

EXETER DIVISION.—At Royal Devon and Exeter Hospital, Thursday, January 24, 8.30 p.m., annual general meeting.

FURNESS DIVISION.—At Orthopaedic Out-patient Department, North Lonsdale Hospital, Tuesday, January 22, 8 p.m., meeting of Barrow and Furness Clinical Society. Mr. W. H. Graham: "Urinary Infections."

HERTFORDSHIRE BRANCH.—At Barnet General Hospital, Wellhouse Lane, Barnet, Friday, January 25, 8.15 p.m., meeting followed by three films: "The Birth of a Drug"; "Pseudo-Pregnancy and Labour"; "A Case of Scurvy."

ISLE OF WIGHT DIVISION.—At Whitecroft Hospital, Sunday, January 20, 3 p.m., lecture by Dr. J. H. L. Conway-Hughes: "The Medical Aspects of Atomic Warfare." All Island practitioners are invited.

OLDHAM DIVISION.—At Oldham Hotel, Rhodes Bank, Monday, January 21, 9 p.m., talk and three films by Mr. O. M. Duthie: (1) "Corneal Transplantation"; (2) "Latest Operation for Retinal Detachment"; (3) "Cataract Surgery."

ROCHESTER, CHATHAM, AND GILLINGHAM DIVISION.—At St. Bartholomew's Hospital, Rochester, Thursday, January 24, 8 p.m., lecture by Dr. H. Yellowlees: "Hypnotism: Its Uses and Limitations in Medicine." All medical practitioners in the area of the Division are invited.

SALISBURY DIVISION.—At Hulse Clinic, Salisbury Infirmary, Tuesday, January 22, 8.15 p.m., clinical evening by Dr. J. H. Gubbin and Dr. R. G. M. Longridge.

TOWER HAMLETS DIVISION.—At St. Andrew's Hospital, Bow, E., January 25, 3 p.m.; orthopaedic demonstration by Mr. E. T. Bailey.

WEMBLEY DIVISION.—At Sudbury Arms, Tuesday, January 22, 8.30 for 9 p.m., meeting. "A Medical Brains Trust."

WIGAN DIVISION.—At The Hollies, Wigan Lane, Wigan, Thursday, January 24, 8.15 p.m., clinical meeting. New medical film in sound and colour: "Peripheral Vascular Diseases."

A combination of qualities

The claims of 'Dettol' do not rest on any single quality desirable in an antiseptic, but rather upon the combination of several essential properties. It can be used at fully effective strengths with safety; without risk of poisoning, discomfort or damage to tissue. It retains a high bactericidal potency in the presence of blood, it is stable, and agreeable in use.

'DETTOL' **THE MODERN ANTISEPTIC**

'Dettol' is available in 2 gallon and 5 gallon tins free of Purchase Tax for *dispensing purposes only*. Smaller sizes, including 1 gallon tins for public use are subject to Purchase Tax.

A new analgesic

Synthesized in the Roche research laboratories, the compound 3-hydroxy-N-methyl-morphinan was found to have a greater analgesic effect than morphine. The drug has been given the approved name methorphan. It has now been introduced under the trade mark

More potent and longer-acting than morphine—

Effective by mouth

DROMORAN

Available as the 1-tartrate in tablets of 1.5 mg. for oral use and in ampoules containing 2.0 mg. in 1 c.c. for injection. Tablets in packings of 20 and 200. Ampoules in packings of 6 and 50.

Subject to D.D.A. Regulations

ROCHE PRODUCTS LIMITED
Welwyn Garden City, Herts.
